Summary Bronchopulmonary Dysplasia (BPD) is a rare chronic lung disease and one of the most difficult complications to treat in premature infants. With the progress at the medical treatment level, an increasing number of BPD premature infants are born, meanwhile, they would be at an increasing risk for numerous complications and rehospitalization because BPD affects many vital organ systems. The pathogenesis of BPD is clearly multifactorial. As the prognosis is closely connected with the severity of BPD, early diagnosis and treatment are of great help to control the development of BPD. This article focuses on risk factors that could influence the severity of BPD in order to provide a reliable basis for early diagnosis, treatment, and better patient assessment.

Keywords: Bronchopulmonary dysplasia, preterm infants, risk factors

1. Introduction

Bronchopulmonary dysplasia (BPD) is a rare chronic lung disease in premature infants resulting from oxygen and mechanical ventilation that was first described by Northway et al. in 1967 (1). BPD has become one of the thorniest issues in the neonatal intensive care unit (NICU) and the main cause of chronic respiratory diseases of infants due to auxiliary oxygen for a long time, a high mortality rate, survivors with high reactive airway disease, feeding difficulties and growth retardation. Children with BPD need long-term dependence on oxygen which, easily causes repeated infection of the lung and even leads to physical and intellectual developmental disorders. BPD seriously affects the survival rate and living quality of premature infants and, it brings a heavy burden to the family and society. The reported incidence of BPD was quite different in various studies. Possible reasons were differences in clinical definitions (2), demographics of patient populations and management strategies used across studies (3). There are about 3,000 ~ 7,000 newborns suffering from BPD in America every year (4), however, the morbidity is not clear in China. Many questions about the etiology and pathogenesis of BPD still remain in spite of a mountain of extensive research that has been done which aimed at identifying risk factors of BPD and planning preventative therapies (5). The foremost predictor for BPD development is prematurity, yet many other factors may contribute.

In order to study the risk factors which could influence the severity of BPD in premature infants and provide reliable bases for effective prevention and control measures, this research conducted a retrospective analysis concerning the clinical data and inspection results interrelated information of 47 cases. In addition, we also hope to develop better practices in the management of newborns with BPD in the future.

2. Methods

2.1. Objects

These cases were selected from the rare diseases database which was established through the pilot project launched by China (6). There were 51 BPD infants registered in the database in total from 1st January
2012 to 31st November 2014. Term infants, cases with congenital anomalies, metabolic or neuromuscular diseases were excluded. Finally, this study consisted of 47 premature infants who were diagnosed with BPD and registered in the database from 2012 to 2014. There were 33 baby boys (70%) and 14 baby girls (30%). All cases corresponded with the BPD diagnosis standard which was formulated by American National Child Health and Human Development Institute (NICHD) in 2000 (7). A total of 28 (59%) infants had mild BPD, 13 (28%) moderate BPD, and 6 (13%) with severe BPD. The classification standard of severity was also formulated by NICHD (7). Database records included antenatal, natal, and postnatal features together with the laboratory findings of the infants.

2.2. Data processing and analysis

SPSS 17.0 was used to input and manage data. Repeated cases have been excluded. Enumeration data was analyzed by chi-square test (Fischer's exact probability test) and measurement data was analyzed by variance analysis. The 95% confidence interval (CI) and p value were acquired by single factor analysis. In this study, we also used the classification of BPD as dependent variable and all factors with significant associations emerging from the univariate analysis as independent variables to conduct an ordinal logistic regression analysis. The difference was statistically significant when $p < 0.05$. Charts were then drawn with SPSS and Excel.

3. Results

3.1. Antenatal features

As shown in Table 1, the differences were statistically significant when the pregnant mothers had chorioamnionitis and history of abnormal pregnancy. Repeated abortion history, placenta previa, placental abruption, polyhydramnios, oligohydramnios, edema-hypertension-proteinuria syndrome, etc were included in the abnormal pregnancy group.

3.2. Natal features

Statistical analysis results showed that the smaller the gestational age and the lower the birth weight are, the higher the severity. The results displayed that multiple births didn't have statistical significance despite three sets of twins that suffered from BPD. In the meantime, gender, delivery mode and intrauterine infection pneumonia didn't influence the severity of BPD according to the value of $p$. All the natal features are shown in Table 2.

3.3. Postnatal characteristics

Abnormal coagulation function, cholestasis, NRDS and acidosis could affect the severity of BPD among postnatal factors while severity of anemia, HIE, disorders of glucose metabolism and hypoproteinemia were not

influence factors with statistical significance (Table 3). There were 13 mild, 9 moderate and 5 severe cases taken electrocardiographic examinations in total. In the echocardiography results, patent ductus arteriosus could influence severity compared with patent foramen ovale after statistical verification.

3.4. Ordered logistic regression analysis about influence factors of BPD

Through single factor analysis, 9 factors had statistical significance including: chorioamnionitis, history of abnormal pregnancy, gestational age, birth weight, abnormal coagulation function, cholestasis, NRDS, acidosis and patent ductus arteriosus. In this study, only 27 patients accepted vascular ultrasonography and valid data was too small. Because it didn't meet the conditions of ordered logistic regression analysis, the factor was excluded. By means of ordered logistic regression analysis, chorioamnionitis, history of abnormal pregnancy, abnormal coagulation function, and cholestasis were independent factors which could influence the severity of BPD (Table 4).

4. Discussion

After nearly 5 decades since the first description of BPD by Northway, its epidemiology, clinical presentation and pathogenesis have changed. BPD was a chronic lung disease associated with premature birth and still lacked effective prevention and treatment (9). The etiology and pathogenesis were still unclear and most scholars believed that the occurrence and development of BPD were associated with premature birth, inhalation of high concentrations of oxygen, long duration of mechanical ventilation and infection (10). Immature lung development at an early gestational age and light weight infants were the most basic factors for the occurrence of BPD (11-15). This study also showed BPD was more serious when the gestational age was earlier and birth weight was lower owing to immature lung development and respiratory function.

Our study showed that there is a relationship between the severity of BPD and PDA. The incidence of heart failure, pulmonary edema, etc. increased in BPD infants with PDA. It was due to PDA could also significantly increase blood circulation in lung tissue, probability of edema and infection of lung tissue. PDA and BPD may be a cause and effect relationship. Some researchers came to the same conclusion (16). Respiratory distress syndrome (RDS) is a common cause of morbidity and mortality related to premature birth and most infants who develop BPD initially suffer from acute RDS (17). Infants with RDS may easily have acidosis due to adverse pulmonary ventilation. The present study shows, as we expected, that RDS and acidosis are associated with the severity of BPD.

Chorioamnionitis was an independent risk factor in our study. When pregnant women have chorioamnionitis, the expression levels of the proinflammatory cytokines
increased significantly which could also cause a fetal pulmonary inflammatory reaction or even systemic inflammatory response syndrome. Pulmonary edema, abnormal deposition of fibrin and a decrease of the biological activity of pulmonary surfactant were caused by the pathological process. Inflammatory cytokines in amniotic fluid get into the fetal lung when the mother has chorioamnionitis and caused lung inflammation and injury. The injury continued development after birth and the infants finally developed BPD (18).

Our findings indicated that women with a history of abnormal pregnancy (abortion, stillbirth and premature birth) was another risk factor which could influence the severity of BPD. Some scholars believed that pregnant women with an abnormal childbearing history was a potential risk factor for BPD (19), but yet no studies showed that abnormal pregnancy was an independent risk factor for the severity of BPD. The endometrium cannot fully repair itself in the short term and a cervical mucus embolism that was erased during the operation could lead bacteria easily into the uterine cavity. A common complication is uterine cervical lesions after abortion and pregnant women are prone to premature birth when they have a subsequent pregnancy because the cervix function is not complete. On the other hand, the endometrial myometrial interface was damaged during the artificial abortion and the placental circulation was disordered which could cause placental insufficiency. Finally, these reasons lead to fetal intrauterine hypoxia, slow growth, premature birth and even stillbirth.

Blood vessels are more vulnerable and coagulation factors are deficient in premature infants. Most premature infants had asphyxia when they were born and the function of the organ and adaptability were weaker compared with term infants which could cause pulmonary, intracranial hemorrhage, etc. Therefore, asphyxia could easily cause disorder of blood coagulation function. The development of reticular endothelial structure is imperfect in prematurities. The structure could release tissue factors when the tissue was damaged which could cause placental insufficiency. Finally, these reasons lead to fetal intrauterine hypoxia, slow growth, premature birth and even stillbirth.

Sepulveda found that cholic acid in high concentrations could constrict blood vessels (22) which would lead to a decrease in pulmonary blood flow and even pulmonary hypoxia. Some researchers figured that cholic acid may cause lung damage through hindering the synthesis of pulmonary surfactant and cause an inflammatory reaction (20,23). These above researches explained how cholestasis could injure the development of the lung which may even cause the occurrence of BPD.

5. Conclusion

Due to an improvement in the survival of ELBW infants, BPD has been increasing over the past several decades. Because BPD arises from multiple pathogenic processes in the preterm lung which probably cause various results, various aspects of care need meticulous assessment. It originates from the interaction of multiple factors that could injure the immature lung, and for exactly that reason, preventions must be developed on the basis of all the factors implicated in its pathogenesis. The more serious the illness is, the worse the prognosis. Severe BPD could even influence the brain or other vital organs in the long term process. Therefore, we can actively take preventive measures to control disease development according to potential risk factors in the clinical performance.

Our data showed that the most relevant risk factors that could influence the severity of BPD were low birth weight, early gestational age, chorioamnionitis, childbearing history, cholestasis and abnormal coagulation function. Comprehending the case history, especially whether the mother had chorioamnionitis or an abnormal pregnancy history, and careful examination were vital. Mothers who have had abortions many times may give birth to severe BPD infants to a greater extent. The birth of premature infants with low birth weight and early gestational age are more likely to develop severe BPD (24). Paying close observation to the appearance of cholestasis and abnormal coagulation function could control and prevent the progress of the severity of BPD. It is needed that all NICUs keep making efforts to know better practices, decrease risk factors and contribute to the prevention of BPD.
