Aim: Whether clusterin/apolipoprotein J is antiatherogenic or proatherogenic is controversial. We reported that clusterin was markedly induced in media and neointima after vascular injury and that reduced clusterin expression reduced the proliferation of vascular smooth muscle cells (VSMCs), which induced G1 arrest via p53 and p21. The purpose of this study was to investigate the physiological function of clusterin in atherosclerosis using double-knockout mice (D-KO) of apolipoprotein E-deficient mice (apoE-KO) and clusterin-deficient mice (CLU-KO).

Methods and Results: Atherosclerotic lesions in the aortic root were quantitated at 20 weeks of age. Atherosclerotic lesions of D-KO were significantly smaller than those of apoE-KO (D-KO: 0.176 ± 0.078 mm² vs. apoE-KO: 0.365 ± 0.164 mm², p < 0.001). To identify underlying atherosclerotic mechanisms that were blocked by loss of clusterin, we performed immunohistochemical analysis of Egr-1. Egr-1 immunoreactivity in the nuclei of VSMCs in atherosclerotic lesions of apoE-KO was upregulated, whereas it was not in D-KO lesions. Western blotting demonstrated that the expression levels of Egr-1 and TNF-α in the D-KO were significantly lower than those in the apoE-KO. When VSMCs and macrophages were obtained from D-KO and apoE-KO, Western blotting showed that the expression levels of Egr-1 and TNF-α in VSMCs and macrophages of D-KO were significantly lower than those of apoE-KO.

Conclusion: Loss of clusterin strongly suppressed apoE-KO-induced atherosclerotic lesions at a step prior to the expression of Egr-1 and TNF-α, suggesting that clusterin is a candidate for an antiatherogenic target.

Key words: Clusterin, Atherosclerosis, Egr-1, TNF-α

Introduction

Atherosclerosis is a progressive disease characterized by the accumulation of lipids and fibrous elements in the large arteries and constitutes the single most important contributor to the growing burden of cardiovascular disease1. Atherosclerosis is an inflam-
cells. Furthermore, clusterin is found in all body fluids, including plasma, seminal plasma, milk, urine, and cerebrospinal fluid. The wide distribution and sequence conservation of clusterin suggest that this protein performs functions of fundamental biological importance. It is involved in numerous physiological processes important for carcinogenesis and tumor growth, including apoptotic cell death, cell cycle regulation, DNA repair, cell adhesion, tissue remodeling, lipid transportation, membrane recycling, and immune system regulation. Furthermore, the expression of clusterin is upregulated in acute myocardial infarction, atherosclerosis, myocarditis, Alzheimer’s disease, several cancers, oxidative stress, heat shock, and after injury in general.

We reported that clusterin was markedly induced in media and neointima after vascular injury and that the expression of clusterin stimulated the proliferation and migration of cultured VSMCs in vitro. In addition, Millis et al. reported that clusterin regulates VSMC nodule formation and migration. Moreover, clusterin antisense was reported to inhibit the proliferation of cultured VSMCs obtained from neointima after ballooning in vitro. Recently, we reported that reduced clusterin expression reduced the proliferation of VSMCs and induced G1 arrest via p53 and p21. Although clusterin is expressed in atherosclerosis lesions, it is not clear whether it is antiatherogenic or proatherogenic.

The purpose of this study was to investigate the physiological function of clusterin in atherosclerosis using double-knockout mice (D-KO) of apolipoprotein E-deficient mice (apoE-KO) and clusterin-deficient mice (CLU-KO).

Materials and Methods

Generation of CLU−/−/apoE−/− Double-Knockout Mice (D-KO)

We used apoE-KO mice with a C57BL/6 background that were donated by Dr. Jan L. Bresslow (Rockefeller University) and CLU-KO mice with a C57BL/6 background. CLU-KO mice were as described by McLaughlin et al. Unperturbed CLU-KO mice showed a minimal phenotype, including atherosclerosis and inflammation. ApoE-KO mice were crossed with CLU-KO mice and heterozygous knockout mice were crossed until homozygous double-knockout (D-KO) mice were obtained. Genotypes for apoE and clusterin were determined by polymerase chain reaction (PCR) amplification of DNA isolated from the tail. Mice were fed a standard diet and water was available ad libitum. All animal procedures were carried out with the approval of the Animal Research Committee in accordance with the guidelines on animal experiments of the Faculty of Medicine, Kagoshima University. The study conformed to the Guide for the Care and Use of Laboratory Animals published by the United States National Institutes of Health (NIH Publication No. 85-23, revised 1996).

Genotyping by Polymerase Chain Reaction

Clusterin genotyping was performed by PCR analysis using three primers obtained from Sigma-Aldrich Japan (Tokyo, Japan) that amplified both wild-type and mutant alleles in the same reaction. These were: SHF-3 (5'-ACGATGTGAGAGATGTGGAGATGACATG-3') forward primer, recognizing both mutant and wild-type alleles and corresponding to genomic sequences near the 5' end of the short homology fragment; apoJKO-R2 (5'-TGGTGATGGGGGCTCTAGTCACCTCCACATC-3'), reverse wild-type primer complementary to sequences just 3' to the deleted first exon; and PGK-2 (5'-CTGCGACTGCATCTCCAGACTGCTTG-3'), reverse knockout primer corresponding to sequences in the promoter region of the hypoxanthine phosphoribosyl transferase (HPRT) cassette. PCR for wild-type (500 bp) and mutant (540 bp) alleles was performed with cycles consisting of 3 minutes at 94°C, 45 seconds at 52°C, and 45 seconds at 72°C.

Apolipoprotein E genotyping used the following primers (Sigma-Aldrich Japan): antisense, 5'-GGCTAGCCGCCAGAGGAGCCG-3' and sense, 5'-GGCCGCCCCGACTGCTCTCCACAC-3'. Resultant wild-type and deficient allele bands were 155 bp and 245 bp, respectively. PCR was performed with 35 cycles consisting of 3 minutes at 94°C, 40 seconds at 68°C, and 2 minutes at 72°C.

Tissue Preparation and Lesion Assessment

Male double-homozygous (CLU−/−/apoE−/−; D-KO) mice and male apoE knockout (CLU+/−/apoE−/−; apoE-KO) mice were compared in this study. At the age of 20 weeks, mice were anesthetized with pentobarbital (80 µg/kg body weight, intraperitoneally) and fasting blood was drawn from the left ventricle of the anesthetized mice. Plasma total cholesterol, triglyceride, and HDL cholesterol levels were measured with an enzymatic kit (Kainos, Tokyo, Japan).

After blood drawing, mice were perfused with phosphate-buffered saline (pH 7.4) followed by 10% neutral-buffered formalin through a catheter placed in the left ventricle. The heart with the aortic root was fixed in 10% neutral-buffered formalin, embedded in OCT, and frozen at −80°C. Frozen sections were cut...
into 10-μm sections and fixed to glass slides. The slides were stained with oil red O. All sections were examined under a microscope; the lipid staining of the aortic root in the histological sections was quantitated.

**Immunohistochemical Analysis**

The heart with the aortic root was also paraffin-embedded and stored at room temperature. Immunohistochemical staining was carried out on paraffin-embedded sections as described previously. After deparaffinization and hydration of specimens, the endogenous peroxidase activity was blocked and the specimens were fixed by immersion in 0.3% H₂O₂ in methanol for 20 minutes. Immunohistochemical staining was performed with a rabbit polyclonal antibody against human Egr-1 (Santa Cruz Biotechnology, Santa Cruz, CA) using the labeled streptavidin biotin complex method (Simple-stain MAX-PO kit, Nichirei, Tokyo, Japan). After blocking with 10% rabbit or goat serum, slides were incubated overnight with a primary antibody at 4°C in a moisture chamber. Slides were washed with Tris-buffered saline and incubated with a biotinylated secondary antibody at room temperature for 30 minutes. After washing with Tris-buffered saline, slides were incubated with streptavidin at room temperature for 30 minutes and visualized with 3,3′-diaminobenzidine.

**Western Blot Analysis**

Protein was extracted from the aorta of apoE-KO or D-KO mice using the Protein and RNA Isolation System (Ambion Inc., Austin, TX). Insoluble matter was removed by centrifugation and the protein concentration was measured by a bicinchoninic acid assay (PIERCE Biotechnology Inc., Rockford, IL). Western blotting was performed with the NuPAGE™ Electrophoresis System (Invitrogen, Carlsbad, CA) as reported previously. Briefly, 10-μg protein samples were resuspended in reduced sample buffer and then electrophoresed on a 4-12% Bis-Tris gel (Invitrogen, Carlsbad, CA) with 3-(N-morpholino) propanesulfonic acid (MOPS) running buffer and blotted on to a nitrocellulose membrane. The protein sample was then sequentially probed with a rabbit polyclonal antibody against human clusterin, ERK1, Egr-1, TNF-α, and actin (Santa Cruz Biotechnology). Horseradish peroxidase-conjugated donkey anti-rabbit antibody (Santa Cruz Biotechnology) was then added and the secondary antibody was detected by autoradiography using enhanced chemiluminescence (ECL Plus; GE Healthcare UK Ltd., Little Chalfont, UK). Densitometric analysis was performed to quantitate Egr-1, TNF-α, and actin protein using NIH imaging software. Actin protein was used as a reference for quantitation of Egr-1 and TNF-α protein.

**Cell Experiments**

Primary VSMCs were explanted from the medial layer of each apoE-KO or D-KO mouse aorta as described previously. They were cultured in 75-cm² flasks for continuous growth at 37°C in a humidified atmosphere of 95% air and 5% CO₂ with medium changes every 3 days. The growth medium consisted of Dulbecco’s modified Eagle’s Medium (DMEM) (Invitrogen) supplemented with 10% fetal bovine serum (FBS; SAFC Biosciences, Wicklow, Ireland), 100 units/mL penicillin, and 100 mg/mL streptomycin (Invitrogen). The VSMCs used for experiments were from the third to seventh passages. At 48 hours of incubation, the cells were harvested by trypsinization and counted in a CDA-500 Particle Analyzer (SYSMEX CORPORATION, Hyogo, Japan). At 48 hours of incubation, cytoplasmic and nuclear proteins were extracted from cultured VSMCs using the Protein and RNA Isolation System.

Peritoneal macrophages were recruited and collected from the peritoneal cavities of mice. We injected 5 mL of ice-cold PBS into the peritoneal cavity and harvested by lavage of the peritoneal cavity. The cells from 5 mice were incubated in DMEM supplemented with 10% FBS in 75-cm² flasks at 37°C in a humidified atmosphere of 95% air and 5% CO₂ for 12 hours. Then, 4 hours after adding lipopolysaccharide (LPS; 25 ng/mL), cytoplasmic and nuclear proteins were extracted from cultured macrophages using the Protein and RNA Isolation System. We examined the expression levels of Egr-1 and TNF-α in VSMCs and macrophages as described in the section on Western blot analysis.

**Statistical Analysis**

All calculated data are presented as the mean ± SD. Statistical significance was evaluated using the unpaired Student’s t-test for comparisons between two groups. A probability value of p < 0.05 was considered statistically significant.

**Results**

**Body Weight and Lipid Concentrations**

At 20 weeks old, there were no significant differences in body weight (apoE-KO: 27.5 ± 4.0 g vs. D-KO: 25.3 ± 1.8 g, n = 15 in each group, Fig. 1A) and total cholesterol (apoE-KO: 554.7 ± 160 mg/dL vs. D-KO: 576.5 ± 161 mg/dL, n = 15 in each group,
Fig. 1. Body weight and lipid concentrations at 20 weeks old in apoE-KO (apoE<sup>−/−</sup>) and D-KO (CLU<sup>−/−</sup>/apoE<sup>−/−</sup>) mice. There were no significant differences in body weight (A), total cholesterol (B), HDL cholesterol (C), and triglyceride (D) concentrations at 20 weeks old between apoE-KO mice (n=15 mice, black bars) and D-KO mice (n=15 mice, white bars).

Fig. 1B), HDL cholesterol (apoE-KO: 12.5 ± 7.0 mg/dL vs. D-KO: 10.6 ± 4.5 mg/dL, n=15 in each group, Fig. 1C), and triglyceride (apoE-KO: 119.3 ± 57.3 mg/dL vs. D-KO: 100.1 ± 47.7 mg/dL, n=15 in each group, Fig. 1D) concentrations between the apoE-KO and D-KO mice. In addition, there were no differences in blood sugar levels, blood cell counts and anatomical subjects between apoE-KO and D-KO mice.

Atherosclerotic Lesions

We analyzed atherosclerotic lesions in the aortic roots. Fig. 2A shows representative oil red O-stained cross-sections of the aortic roots of apoE-KO and D-KO mice at 20 weeks old. The atherosclerotic area of D-KO mice was smaller than that of apoE-KO mice. The quantification of the atherosclerotic area in the aortic root revealed that the atherosclerotic lesion of D-KO mice was significantly smaller than that of apoE-KO mice (apoE-KO: 0.34 ± 0.18 mm<sup>2</sup> vs. D-KO: 0.18 ± 0.10 mm<sup>2</sup>, p<0.05, n=15 in each group, Fig. 2B).

Immunohistochemistry

We performed immunohistochemical staining using a primary antibody against Egr-1, which is an atherogenic factor and a promoter of clusterin. The expression of Egr-1 in atherosclerotic lesions of D-KO mice was lower than that of apoE-KO mice (Fig. 3A).

Western Blotting

We isolated protein from the aortas of apoE-KO or D-KO mice at 20 weeks old and used it for Western blotting. We confirmed that clusterin was expressed in atherosclerotic aorta of apoE-KO mice and was not detected in D-KO mice. Densitometric analysis of Western blotting demonstrated that the expression levels of ERK, Egr-1, and TNF-α in D-KO mice were significantly lower than those in apoE-KO mice (ERK: apoE-KO 1.25 ± 0.12 vs. D-KO 0.14 ± 0.07, p<0.05; Egr-1: apoE-KO 1.07 ± 0.10 vs. D-KO 0.19 ± 0.03, p<0.05; TNF-α: apoE-KO 0.21 ± 0.03 vs. D-KO
Loss of Clusterin Limits Atherosclerosis

0.10±0.03, p<0.05, n=3 in each group, Fig. 3B). These results suggested that clusterin deficiency reduced the expression of the Egr-1/TNF-α pathway.

Cell Experiment
Cultured VSMCs were explanted from the thoracic aortas obtained from apoE-KO or D-KO mice. After 48 hours of incubation, the cell number of VSMCs obtained from D-KO mice (D-KO VSMCs) was significantly smaller than that from apoE-KO mice (apoE-KO VSMCs) (apoE-KO VSMCs: 10,165 ± 822 cells versus D-KO VSMCs: 6,825 ± 485 cells, p<0.05, Fig. 4A). Western blotting demonstrated that the expression levels of Egr-1 and TNF-α of D-KO VSMCs were significantly lower than those of apoE-KO VSMCs (Egr-1: apoE-KO 0.73±0.14 vs. D-KO 0.30±0.11, p<0.05; TNF-α: apoE-KO 0.17 ±0.01 vs. D-KO 0.09±0.02, p<0.05, n=3 in each group, Fig. 4B, C).

Furthermore, we analyzed the expression levels of
Egr-1 and TNF-α in macrophages obtained from apoE-KO or D-KO mice. After stimulation by LPS, Western blotting showed that the expression levels of Egr-1 and TNF-α in macrophages of D-KO mice were significantly lower than those of apoE-KO mice (Egr-1: apoE-KO 0.20 ± 0.03 vs. D-KO 0.12 ± 0.02, p < 0.05; TNF-α: apoE-KO 0.55 ± 0.06 vs. D-KO 0.23 ± 0.04, p < 0.05, n = 3 in each group, Fig. 5).

Discussion

For the first time, we demonstrated that the atherosclerotic lesion of D-KO mice was significantly smaller than that of apoE-KO mice. Moreover, the loss of clusterin reduced the expression of Egr-1 and TNF-α in the atherosclerotic lesion, and cultured VSMCs and macrophages. These results suggested that clusterin is an atherogenic factor.

Clusterin plays a dual role as a tumor suppressor and a tumor promoter. This diverse set of functions can be attributed to the existence of two alternatively spliced forms, secretory clusterin (sCLU) and nuclear clusterin (nCLU)\(^{22}\). The sCLU form is cytoprotective. Recently, Kim et al. reported that sCLU inhibited the proliferation and migration of VSMCs\(^{23}\). In contrast, nCLU migrates to the nucleus upon cytotoxic stress to trigger cell death and interacts with the DNA double-strand break repair antigen Ku70, blocking its function and causing cell death\(^{24}\). In this study, Western blotting demonstrated that nCLU, a 49-kDa protein expressed in the atherosclerosis of apoE-KO mice, and reduced nCLU expression reduced the atherosclerotic lesions of apoE-KO mice.

Egr-1 is a promoter of clusterin and contributes to the pathogenesis of atherosclerotic lesions\(^{25}\). Subsequent studies comparing Egr-1 protein expression in cells derived from the human atherosclerotic lesion and media at low passage revealed greater expression in lesions\(^{26}\). The lesion area in mice deficient in both Egr-1 and apoE is markedly reduced compared with that in mice lacking apoE alone\(^{27}\). Egr-1 is also found in inflammatory cells of vascular lesions. For example, Egr-1 is expressed in CD68+ macrophages of aortic atherosclerotic lesions in fructose-fed low-density lipoprotein receptor-deficient mice\(^{28}\). Thus, Egr-1 is found in several cell types within atherosclerotic lesions and is a factor required in atherogenesis. TNF-α, IL-2, MCP-1, and ICAM-1 are Egr-1 target genes\(^{29}\). We demonstrated that loss of clusterin reduced the activation of Egr-1/TNF-α in VSMCs and macrophages and reduced the atherosclerotic lesions.

Clusterin exerts a feed-forward loop including ERK activation, which leads to the up-regulation of Egr-1 and clusterin\(^{30}\). We confirmed that the expression of ERK and Egr-1 was down-regulated in atherosclerotic lesions of D-KO mice; therefore, we think that the down-regulation of clusterin leads to the reduction of Egr-1 via down-regulation of ERK.

We demonstrated that the proliferation of VSMC in D-KO was reduced. In addition, we showed the down-regulation of Egr-1 and TNF-α of D-KO VSMCs. These results suggest that clusterin deficiency down-regulates the expression of Egr-1 and TNF-α, which leads to the suppression of VSMC proliferation.

Macrophages play an important role in atherosclerosis. We demonstrated that the expression of Egr-1 and TNF-α was down-regulated in macrophages obtained from D-KO mice; therefore, the reduction of Egr-1 and TNF-α expression in macrophages may also lead to the reduction of atherosclerosis in D-KO mice.

Fig. 5. Western blotting for Egr-1, TNF-α, and β-actin of peritoneal macrophages from apoE-KO (apoE−/−) or D-KO (CLU−/−/apoE−/−) mice.
A: Representative Western blot analysis for Egr-1, TNF-α, and β-actin of peritoneal macrophages from apoE-KO mice (n = 3 experiments, black bar) and D-KO mice (n = 3 experiments, white bar). B. Densitometric analysis of Western blotting demonstrated that the expression levels of Egr-1 and TNF-α in macrophages from D-KO mice (n = 3 experiments, white bar) were significantly lower than those from apoE-KO mice (n = 3 experiments, black bar). \(* p<0.005\) versus apoE-KO mice.
In addition, clusterin is reported to inhibit the migration and adhesion of human umbilical vein endothelial cells\(^{33}\).

Clusterin is identical to apolipoprotein J; however, there were no significant differences in total cholesterol, HDL cholesterol, and triglyceride levels between apoE-KO and D-KO. Therefore, we think that clusterin deficiency did not reduce atherosclerosis via lipoprotein metabolism in this study.

Intravenous infusion of the antisense oligonucleotide of clusterin, which is called OGX-011, has been approved for clinical phase III trials in prostate cancer. OGX-011 may be used for the prevention or regression of atherosclerosis.

In conclusion, loss of clusterin strongly suppressed apoE-KO induced atherosclerotic lesions at a step prior to the expression of Egr-1 and TNF-\(\alpha\), suggesting that clusterin is a candidate for an antiatherogenic target.
