Aim: Sitosterolemia is an extremely rare, autosomal recessive disease characterized by high plasma sterols and plant sterols because of increased absorption of dietary sterols from the intestine, and decreased excretion by biliary tract. Previous study indicated that sitosterolemic patients might be vulnerable to post-prandial hyperlipidemia, including high remnant-like lipoprotein particles (RLP) levels. Here we evaluate whether a loading dietary fat increases a post-prandial RLP cholesterol level in sitosterolemic patients compared to heterozygous familial hypercholesterolemic patients (FH).

Methods: We recruit total of 20 patients: 5 patients with homozygous sitosterolemia, 5 patients with heterozygous sitosterolemia, and 10 patients with heterozygous FH as controls from May 2015 to March 2018 at Kanazawa University Hospital, Japan. All patients receive Oral Fat Tolerance Test (OFTT) cream (50 g/body square meter, orally only once, and the cream includes 34% of fat, 74 mg of cholesterol, and rich in palmitic and oleic acids. The primary endpoint is the change of a RLP cholesterol level after OFTT cream loading between sitosterolemia and FH. We measure them at baseline, and 2, 4, and 6 hours after the oral fat loading.

Results: This is the first study to evaluate whether sitosterolemia patients have a higher post-prandial RLP cholesterol level compared to heterozygous FH patients.

Conclusion: The result may become an additional evidence to restrict dietary cholesterols for sitosterolemia. This study is registered at University Hospital Medical Information Network (UMIN) Clinical Trials Registry (UMIN ID: UMIN000020330).

Key words: Sitosterolemia, Familial hypercholesterolemia, Post-prandial hyperlipidemia

Introduction

Sitosterolemia (OMIM #210250) is an extremely rare, autosomal recessive disease characterized by high plasma plant sterols because of increased absorption of dietary sterols from the intestine, and decreased excretion by biliary tract. Sitosterolemic patients also have a higher plasma low-density lipoprotein cholesterol (LDL-C) level, tendon xanthomas, premature atherosclerosis, and coronary artery disease (CAD), resembling familial hypercholesterolemia (FH). FH is mainly caused by loss-of-function variants in LDLR gene. On the other hand, inactivating variants in ATP-binding cassette transporter G5 (ABCG5) and G8 (ABCG8) genes cause sitosterolemia.

Recently, we reported several sitosterolemic patients, including infants with extremely high LDL-C levels after breastfeeding. This report indicates that patients with sitosterolemia might be vulnerable to post-prandial hyperlipidemia, especially high remnant-like particle (RLP) levels. RLP levels are known as a rapid marker to evaluate lipid metabolism after diet. Also, increased RLP levels are associated with high LDL-C, endothelium dysfunction, and CAD. Thus, this post-prandial condition may play an important role of plasma high LDL-C levels and promote atherosclerosis for sitosterolemic patients.
We also assess the adverse effects of the test after 4 weeks (Fig. 1). Overall assessment protocol of this study is shown in Table 1.

We recruit sitosterolemia and FH patients from May 2015 to March 2018, or until the enrollments completed. This study is registered at University Hospital Medical Information Network (UMIN) Clinical Trials Registry (UMIN ID: UMIN000020330).

We conduct this study in compliance with the Declaration of Helsinki, the Ethical Guidelines for Medical and Health Research Involving Human Subjects, and all other applicable laws and guidelines in Japan. This protocol was approved by the institutional review board (IRB) at the Kanazawa University Hospital.

**Study Participants**

We include the patients who meet all the inclusion criteria (Table 2). Patients with either of the exclusion criteria are excluded from this study (Table 3). We obtain written informed consents from all the study participants. For children’s participation, we prepare a parental consent form to obtain their parental or guardian's permissions. These consent forms were approved by IRB. The study participants must sufficiently understand the contents of the consent form before his/her acceptance. It must be dated and signed by both the participants and investigators. We also inform participants that their medical care will not be affected if they refuse to enroll in this study. We store these consent forms at Kanazawa University Graduate School of Medicine. Participants can drop from this study whenever they want to discontinue the study.

**Definitions of Diseases**

*Sitosterolemia diagnostic criteria*:\(^{19, 20}\):

A. **Clinical diagnosis criteria:**
- Patients with all the following criteria:
  1) Plasma sitosterol level of \(\geq 10\ \mu\text{g/mL}\)
  2) Tendon xanthoma or xanthoma tuberosum

B. **Genetic diagnosis criteria:**
- B-1) Heterozygous sitosterolemia: heterozygous loss-of-function variant in the genes
- B-2) Homozygous sitosterolemia (true sitosterolemia): True homozygous, compound heterozygous, or double heterozygous loss-of-function variants in the genes

Patients who meet both A and B-1 are defined as heterozygous sitosterolemia.
Patients who meet both A and B-2 are defined as homozygous sitosterolemia.

**Methods**

**Study Design**

This study is a single arm, non-randomized, open label, uncontrolled trial. Patients with homozygous sitosterolemia, heterozygous sitosterolemia, and heterozygous FH are enrolled. Heterozygous FH patients are used as controls to arrange baseline cholesterol levels in this study. They receive an Oral Fat Tolerance Test (OFTT) cream when inclusion criteria are met. We then compare post-prandial plasma RLP cholesterol levels between homozygous sitosterolemia, heterozygous sitosterolemia, and heterozygous FH.

![Fig. 1. Scheme of this study protocol](image)

Abbreviations: FH, familial hypercholesterolemia; hrs, hours; OFTT, Oral Fat Tolerance Test; wks, weeks.

However, it has not been clear whether the post-prandial high RLP levels truly exist in sitosterolemia patients.

Here, we evaluate for the first time whether a loading dietary fat increases post-prandial high RLP levels in patients having sitosterolemia compared with those having FH.

- High sensitivity CRP
- Symptoms

Abbreviations: ALT, alanine aminotransferase; AST, aspartate aminotransferase; BUN, blood urea nitrogen; CBC, complete blood count; Cr, creatinine; CRP, C-reactive protein; γ-GTP, gamma-glutamyl transpeptidase; HDL, high-density lipoprotein; LDL, low-density lipoprotein; OFTT, Oral Fat Tolerance Test; RLP, remnant-like lipoprotein particle.

Heterozygous FH diagnostic criteria:

A. Clinical diagnosis criteria:

Patients (≥ 15 years old) with more than or equal to 2 following criteria:
1) Untreated LDL cholesterol level of ≥ 180 mg/dL
2) Tendon xanthoma or xanthoma tuberosum

3) Family history of FH or premature CAD within second-degree relatives

Patients (< 15 years old) with all the following criteria:
1) Untreated LDL cholesterol level of ≥ 140 mg/dL
2) Family history of FH or premature CAD within
OFTT Cream Loading
All patients receive OFTT cream (50 g/body surface area square meter, orally only once)\textsuperscript{14, 15, 24} after a 12-hour overnight fast, either before the lipid-lowering treatment or after discontinuation of medication for at least 4 weeks. The cream includes 34% of fat, 74 mg of cholesterol (341 kcal/100 g), and is rich in palmitic [C16:0] and oleic [C18:1] acids.

Safety Monitoring
We check all unfavorable or unintended events/symptoms for patients as well as study investigators through this study period. It does not matter if the events are associated with this study or not. In terms of OFTT cream, it may cause gastrointestinal symptoms such as nausea, vomiting, and diarrhea.

Data Management
Patients’ clinical data and blood samples are coded with study-specific identification number. RLP cholesterol and apolipoproteins are measured at a central clinical laboratory (SRL, Inc, Tokyo, Japan). Plasma concentrations of TC, TG, and HDL cholesterol are determined enzymatically. LDL-C level is calculated using the Friedewald equation\textsuperscript{25, 26} for those with triglycerides $\leq$ 400 mg/dL. If triglycerides $\geq$ 400 mg/dL, plasma LDL-C level is directly measured (Sekisui Medical, Tokyo, Japan). We determine plasma sterol levels using gas–liquid chromatography–mass spectrometry\textsuperscript{27}.

Abbreviations as Table 1.
Sample Size

We recruit a total of 20 patients: 5 patients of homozygous sitosterolemia; 5 patients of heterozygous sitosterolemia; and 10 patients of heterozygous FH as controls. Since homozygous sitosterolemia is an extremely rare disease (1 in 1 million), it is impossible to recruit more subjects.

Statistical Analysis

We compare outcomes between the sitosterolemic group and FH group. For continuous variables, we use Mann–Whitney U test to compare continuous variables between two groups. We also use a linear regression if adjustments are needed.

Discussion and Conclusion

This is the first study to evaluate whether sitosterolemia patients have a higher post-prandial RLP cholesterol level compared to heterozygous FH patients.

In terms of mechanisms for higher cholesterol levels, FH patients have high LDL-C levels mainly because of losing function of LDL receptor at liver9). On the other hand, sitosterolemic patients have high LDL-C levels because of dysfunction of ABCG5/ABCG8 in intestine and biliary tract, that leads to inappropriate absorption and excretion of cholesterol11). These conditions indicate that unlike FH, cholesterol levels in sitosterolemic patients are sensitive to dietary cholesterols. Indeed, our previous study supported this idea—breast feeding, which contained high cholesterols and sterols, could cause very high LDL-C levels in patients with infantile sitosterolemia13). If they are truly vulnerable to dietary cholesterols, post-prandial RLP cholesterol levels of sitos- terolemic patients should be increased after oral fat loading, compared to FH patients.

This hypothesis also points out that it might be possible for sitosterolemic patients to lower their cho- lesterol levels by fat-restricted diet. In addition, it may become an additional clinical evidence to cut off dietary cholesterols for patients with sitosterolemia to potentially prevent high plasma LDL-C and future atherosclerosis.

Disclosures

Akihiro Nomura has nothing to disclose. Hayato Tada has received research scholarship from Takeda Science Foundation, Mochida Memorial Foundation, Japan Research Promotion Society for Cardiovascular Diseases, Sanofi K.K, and Astellas Foundation for Research on Metabolic Disorders.
