Key Words: Mass Transfer Coefficient, Droplet Diameter, Hydrolysis Reaction, Mixing Vessel, Ester, Liquid Liquid System

The continuous-phase mass transfer volumetric coefficient \( k_L \) in a liquid-liquid mixing vessel was measured by using the hydrolysis reaction of both \( n \)-amyl and \( n \)-hexyl acetates with sodium hydroxide. Droplet diameter was also observed by using a video recorder via a microscope during the reaction period, allowing the continuous-phase mass transfer coefficient, \( k_L \), to be determined. The coefficient obtained was 2-5 times larger than that obtained from the correlation by Calderbank-Moo Young. Dimensionless correlation of the mass transfer coefficient with the droplet diameter and the power input per unit volume was confirmed experimentally to be close to that for the solid suspension system.

Introduction

For the analysis of a mass transfer-controlled heterogeneous reaction, it is necessary to know both the continuous-phase mass transfer coefficient and the effective interfacial area.

For heterogeneous systems, especially solid-liquid systems, mass transfer through the interface in an agitated vessel has been studied by many investigators\(^{2,3,6,8,9,11}\) and many correlations of the continuous-phase mass transfer coefficient have been proposed.\(^{10}\) Most were based on the local isotropic turbulence theory of Kolmogoroff, though Kuboi et al.\(^{9}\) used the effective relative velocity for mass transfer. For liquid-liquid dispersions, the continuous-phase mass transfer coefficients were studied by Schindler and Treybal\(^{11}\) and Keey and Glen\(^{7}\) for a continuous-flow stirred-tank system and by Skelland and Lee\(^{15}\) for a batch-stirred tank system. Their experiments were, however, conducted under the condition that the droplet size was not in dynamic equilibrium. Nanda and Sharma\(^{10}\) and Sharma and Danckwerts\(^{13}\) proposed a chemical method that gave only the interfacial area of dispersion.

In the present work, the continuous-phase mass transfer coefficient for tiny droplets in dynamic equilibrium is measured by using a reaction method and is compared with the results of previous works and with correlations for the solid-liquid system.

1. Reaction Model

We consider the hydrolysis of ester with alkali\(^{11}\) as a slow reaction.

\[
\text{RCOOR}^\text{+} + \text{NaOH} \rightarrow \text{RCOONa} + \text{R}^\text{+} \text{OH}^- \quad (1)
\]

The following assumptions are made for the present analysis:

i) The ester disperses as droplet in the aqueous phase.

ii) The droplet diameter is constant during the reaction period.

iii) The alkali is mixed well instantaneously when added into the aqueous phase to start the reaction.

iv) The reaction in the concentration boundary film on the droplet surface is negligible compared to the reaction in the bulk of the aqueous phase.

v) The reaction is first-order with respect to the ester and the alkali.

The reaction rates of the ester with the alkali can be expressed as

\[
dC_A/dt = k_1 a(C_{A_i} - C_A) - k_2 C_A C_B \quad (2)
\]

\[
dC_B/dt = -k_2 C_A C_B \quad (3)
\]
At low volume fraction of droplet $\phi$, the apparent concentrations of the ester and the alkali, $C_A$ and $C_B$, can be expressed as

$$C_A = (1 - \phi)C_A + \phi C_A^0 \equiv C_A + \phi C_A^0$$

$$C_B = (1 - \phi)C_B + \phi C_B^0 \equiv C_B + \phi C_B^0$$

(4)

(5)

where $C_A^0$ is the molarity of pure ester.

Initial conditions at $t = 0$ are expressed as

$$C_A = C_{A0} = C_{AS}, \quad C_B = C_{B0} = C_{BO}$$

$$C_A = C_{A0}, \quad C_B = C_{B0}$$

(6)

where subscript "0" means initial value.

From mass balance the apparent concentration of the ester is related to that of the alkali as follows:

$$C_A - C_A = C_{BO} - C_B$$

(7)

From Eq. (4) the following relation can be obtained.

$$\phi/\phi_0 = (C_A - C_{A0})/(C_{A0} - C_{A})$$

(8)

Where the droplet diameter $d_p$ is constant during the reaction period, the interfacial area per unit volume, $a$, is proportional to the volume fraction of the droplet, $\phi$. Then the following expression can be obtained:

$$a/a_0 = \phi/\phi_0 = (C_A - C_{A0})/(C_{A0} - C_A)$$

(9)

Substitution of Eqs. (5), (7) and (9) into Eqs. (2) and (3) gives the following equations:

$$\frac{dC_A^*}{dt^*} = K \left\{ \frac{1 - \theta_B(1 - C_B^*) - C_A^*}{1 - C_A^*} \right\} (C_{A0} - C_{A0}^*) - C_A^* C_B^*$$

(10)

$$\frac{dC_B^*}{dt^*} = -C_A^* C_B^* \theta_B$$

(11)

where

$$C_A^* = C_A/C_{A0}, \quad C_B^* = C_B/C_{B0}, \quad C_{A0}^* = C_{A0}/C_{A0}$$

$$\theta_B = C_{B0}/C_{A0}, \quad K = k_2 a_0 k_2 C_{B0}, \quad t^* = k_2 C_{B0} t$$

(12)

The dimensionless initial conditions are:

$$C_A^* = C_A^0, \quad C_B^* = 1 \text{ at } t^* = 0$$

(13)

Equations (10) and (11) were solved simultaneously by the Runge-Kutta method.

The reaction rate constant $k_2$ and the mass transfer volumetric coefficient $k_1a_0$ were determined by the following method.*

i) The Box complex method is used in obtaining the optimum combination of $k_2$ and $K$ that best fits the observed curve of alkali concentration vs. time.

ii) The reaction rate constant $k_2$ depends only on temperature. Hence the reaction rate constant is determined as the average value of $k_2$ for all runs.

iii) By using the resultant $k_2$, the optimum $K$ value and the mass transfer volumetric coefficient $k_1a_0$ are obtained for each run.

(14)

The initial volume fraction $\phi_0$ is obtained from the mass balance of ester as

$$\phi_0 = \left( \frac{V_A - C_{AS}}{V_A - C_{A0}} \right)$$

(15)

where $V_A$ and $V_W$ are respectively the volumes of pure ester and water added initially to a vessel.

3. Experimental

A schematic diagram of the experimental apparatus is shown in Fig. 1. Agitated glass vessels of 17-, 14- and 10-cm ID were used in the present study. Stainless steel six-blade paddle impellers were used, with diameters of 8.5, 7 and 5 cm. The ratio of impeller to vessel diameter $d/D$ ranged from 0.29 to 0.50.

The ester, n-amyl acetate or n-hexyl acetate, was added to the stirred water to form a dispersed liquid with an apparent ester concentration of 0.025 mol/l. The water was saturated with the ester and the droplet size was in dynamic equilibrium, usually in 10–15 minutes. The initial volume fraction $\phi_0$ defined by Eq. (15) was 0.0017 for n-amyl acetate and 0.0035 for n-hexyl acetate. The reaction was started by instantaneous addition of sodium hydroxide aqueous solution, the concentration of which was adjusted to become 0.050 mol/l in the vessel. At this moment no change in droplet size was observed. The progress of the reaction was monitored by measuring the variation of alkali concentration by electric conductivity meter and by titration.*

The reaction temperature was 25°C or 30°C, and the stirrer speed was 175 to 700 rpm.

For the measurement of droplet diameter, the liquid was sucked up into the focus of a microscope and the droplet picture was recorded with a video-recorder during the reaction period. Each droplet diameter was sized on a microcomputer display and its datum was stored in the computer memory. The Sauter mean diameter $d_{32}$ was obtained from 500 droplet diameters.

---

* As the solubility of $n$-hexyl acetate into aqueous phase is very low, an error in measurement of ester concentration has a significant effect on the evaluation of $k_2$ in a homogeneous system.

* For the titration, the sampled liquid is poured quickly into acidic solution to stop the reaction, then the resultant acidic solution is titrated with alkaline solution. The time lag for sampling is less than three seconds.
at 5-minute intervals.

The physical properties of the esters are listed in Table 1. The diffusivity $D_A$ was estimated from Wilke’s equation,\(^\text{19}\) and the interfacial tension $\sigma$ was measured by the Wilhelmy method.\(^\text{18}\) The solubility $C_{45}$ was observed by using an agitated vessel with a flat liquid-liquid interface, in the same manner as in the previous paper.\(^\text{11}\)

### 4. Results and Discussion

Table 1 also shows the reaction rate constant $k_2$ obtained. The value for $n$-amyl acetate at 25°C was close to the observed value of 0.08051/mol·s for isoamyl acetate byViaillard.\(^\text{17}\)

In Fig. 2 the observed Sauter mean diameter of droplet $d_{32}$ is correlated with the product of impeller diameter and $-0.6$ power of Weber number. The observed diameter is $0.7$ to $2.5 \times 10^{-4}$ m and is slightly larger than that from the correlation by Chen-Middleman.\(^\text{5}\)

The value of $d_{32}$ was almost constant during the reaction period, though the number of droplets in the video-picture decreased with time. Thus the droplet size was presumed to be in dynamic equilibrium.

The value of $k_1d_{0}$ was determined as the average value during the initial reaction period up to 30 minutes, where the dimensionless concentration of the alkali and the volume fraction ratio, $C_{45}'$ and $\phi/\phi_0$, decreased from unity to 0.55 and 0.003 respectively.

The observed mass transfer coefficient is plotted against the power input per unit volume in Fig. 3, where the solid line shows the correlation by Calderbank-MooyYoung\(^\text{4}\):

$$k_L = 0.13(P_r \rho^2/\mu^3)^{0.25}Sc^{-2/3}$$ \hspace{1cm} (16)

The observed mass transfer coefficient is 2–5 times larger than that from Eq. (16). In this figure the experimental data by Schindler and Treyball\(^\text{12}\) for the continuous-flow stirred-tank system are also plotted. They are 2–3 times larger than the present experimental data.

The condition under which the chemical reaction occurs in the bulk of the aqueous phase can be expressed as\(^\text{11}\):

$$k_L > (k_2D_A C_{45})^{1/2}$$ \hspace{1cm} (17)

The value of $k_L$ is larger than $5 \times 10^{-5}$ m/s in Fig. 3, and $(k_2D_A C_{45})^{1/2}$ is smaller than $2.2 \times 10^{-6}$ m/s from Table 1. Then, the present reaction system satisfies the relation of Eq. (17) and the expressions of Eqs. (2) and (3).

Conclusions

For liquid-liquid dispersion of ester in aqueous alkali solution, the continuous-phase mass transfer volumetric coefficient at the droplet surface was measured by using a hydrolysis reaction of the ester with the alkali. The droplet diameter was measured by using a videocamera via a microscope during the reaction period. The continuous-phase mass transfer coefficient was calculated from the observed volumetric coefficient with the droplet diameter. The mass transfer coefficient for the tiny droplet was shown experimentally to satisfy the correlation for suspended
