Serum Thioredoxin (TRX) Levels in Patients With Heart Failure

Chiharu Kishimoto, MD; Keisuke Shioji, MD; Hajime Nakamura, MD*; Yukie Nakayama, BA; Junji Yodoi, MD*; Shigetake Sasayama, MD

An increase in oxidative stress is thought to be involved in the progression of heart disease, but the serum level of thioredoxin (TRX), which regulates the cellular redox state, has not been investigated in patients with heart diseases. The present study determined serum TRX levels with a sandwich enzyme-linked immunoabsorbent assay in a total of 39 patients with dilated cardiomyopathy (DCM) (n=5), acute coronary syndrome (ACS) (n=7) or stable angina (n=18), including effort angina (n=7) and vasospastic angina (n=11), and in control subjects (n=7). The serum TRX level in patients with New York Heart Association (NYHA) functional classes III and IV (n=8, 33.3±8.6 ng/ml) was significantly higher than in the control subjects (n=7, 14.0±4.6 ng/ml). In addition, the serum TRX levels correlated positively with the severity of NYHA class, and negatively with the left ventricular ejection fraction. The serum TRX levels were elevated in patients with ACS and DCM compared with the controls. These results indicate a possible association between TRX concentration and the severity of heart failure. (Jpn Circ J 2001; 65: 491–494)

Key Words: Heart failure; Oxidative stress; Thioredoxin

Many clinical investigations have established that oxidative stress mediated by the generation of reactive oxygen species (ROS) plays an important role in the pathogenesis of coronary artery disease and heart failure. Excessive generation of ROS occurs with myocardial ischemia and reperfusion, and it has been suggested that ROS play a pivotal role in reperfusion injury. In congestive heart failure, myocardial contractility is impaired by either loss of muscle or by pressure or volume overload, which causes myocardial ischemia, resulting in generation of ROS. Heart failure under both acute and chronic conditions is associated with increased oxidative stress, such as superoxide anion and malondialdehyde, and reduced antioxidant reserve, such as superoxide dismutase (SOD), catalase and glutathione reductase. It has been reported that ROS per se may be involved not only in the genesis, but also in the progression, of heart failure, and reported that ROS play a pivotal role in reperfusion injury. Therefore, the addition of antioxidant drugs may be beneficial in the management of heart failure.

Adult T-cell leukemia-derived factor (ADF) is identical to thioredoxin (TRX). TRX has various important biological activities in both the intra- and extracellular compartments. For example, TRX is stress-inducible, which protects cells from various types of stresses (eg, viral infection, exposure to ultraviolet light, X-ray irradiation). Moreover, TRX eliminates hydrogen peroxide and acts as a radical scavenger, and recombinant TRX has a protective activity against hydrogen peroxide cytotoxicity, in which the generation of ROS seems to be involved. TRX suppressed reperfusion-induced arrhythmias in an isolated rat heart model, and overexpression of TRX in transgenic mice was protective for postischemic reperfusion injury in the brain in vivo. However, the levels of TRX that regulate the cellular redox state have not been investigated in human patients with heart diseases. In view of increasing evidence for the involvement of oxidative stress in heart disease, it is interesting to know whether changes in serum TRX levels exist in patients with heart diseases. Therefore, we used an enzyme-linked immunoabsorbent assay (ELISA) to investigate the clinical significance of serum TRX levels in patients with dilated cardiomyopathy (DCM), acute coronary syndrome (ACS) or stable angina (SA), including effort angina (EA) and vasospastic angina (VSA).

Methods

Patients and Control Subjects

Patients and control subjects were all admitted to Kyoto University Hospital between October 1998 and May 2000. The patients were consecutive and their serum samples were available for TRX assay during the study period. The study group comprised 30 patients with DCM (n=5: 3 males, 2 females; age, 53.2±10.5 years, mean±SD), ACS (n=7: 6 males, 1 female; 64.3±8.1 years), and SA including EA (n=7: 5 males, 2 females; 60.3±9.1 years) and VSA (n=11: 10 males, 1 female; 62.8±9.4 years), and 7 control subjects (4 females, 3 males, 62.1±9.1 years; 4 patients with chest pain syndrome, 1 patient with paroxysmal supraventricular tachycardia, 1 patient with paroxysmal atrial flutter, 1 patient with aortic stenosis).
and 1 patient with cerebrovascular accident (CVA)). The study was approved by the Ethics Committee of the Graduate School of Medicine, Kyoto University, and all the patients gave informed consent before entering the study.

The cardiac disability of the patients with heart failure was assessed by New York Heart Association (NYHA) functional class. In all the patients with DCM, coronary angiography and endomyocardial biopsy were performed, and the diagnosis of DCM was made according to standard criteria. Patients with ACS had symptoms of ischemic chest pain at rest within the previous 3 weeks, associated with ECG changes or elevation of creatine kinase-MB isoenzyme. Patients with SA had neither new-onset angina nor accelerated angina during the past month. EA was defined as angina on effort that was associated with transient ST-segment depression, and all these patients underwent coronary angiography and had significant coronary stenosis. VSA was defined as angina at rest that was associated with transient ST-segment elevation or depression, and coronary artery spasm was confirmed by an acetylcholine provocation test.

Serum was obtained from venous blood drawn before breakfast and was stored frozen at −70°C until used.

**Enzyme-Linked Immunosorbent Assay**

The serum TRX levels were measured using a sandwich ELISA kit (FujiRebio Co, Ltd) according to the procedure described previously. Briefly, in ADF 21-antibody-precoated 96-microwell plates, 0.2 ml of blocking buffer (50 mol/L phosphate buffer (PBS), 1% bovine serum albumin, 0.05% Tween-20, pH 6.0) and 0.02 ml of sample were added to the wells and incubated at room temperature for 2 h. After washing 3 times with PBS containing 0.05% Tween-20, 0.2 ml of a 75 ng/ml horseradish peroxidase-labeled anti-ADF 11 antibody was added and incubated at room temperature for 2 h. After washing 5 times with PBS containing 0.05% Tween-20, 100 μl of substrate solution (1.3 mg/ml 2,2-azino-di-3-ethyl-benzthiazoline sulfonic acid dissolved in 0.1 mol/L triethanolamine-succinate buffer containing 15 mmol/L hydrogen peroxide, pH 4.4) was added and incubated for 1 h at room temperature. After 0.1 ml of stopping solution (1% oxalic acid, pH 1.9) was added, the absorption at 405 nm (415 nm) was measured with an ELISA reader (Molecular Devices, Menlo Park, CA, USA). Data were analyzed by SOFTmax Version 2.31 (Molecular Devices).

* p<0.001 vs Control. All data are mean±SD. DCM, dilated cardiomyopathy; ACS, acute coronary syndrome; SA, stable angina; EA, effort angina; VSA, vasospastic angina; TRX, thioredoxin; NYHA, New York Heart Association.

**Statistics**

All the values were expressed as mean±standard deviation (SD). The error bars in the Figures show the SD of the mean. Statistical analyses were performed on a Macintosh computer (PowerBook G3) using StatView 5.0. The statistical significance of observed difference between patients with heart diseases and control subjects was determined by one-way analysis of variance (ANOVA). Any significant groups detected by ANOVA were reanalyzed with Fisher’s protected least significant difference (PLSD) test to characterize significant differences between groups. A value of y=44.365-0.37x r=0.587 p=0.0002

![Comparison of the serum TRX levels among patients with NYHA functional class I (n=17, 19.1±8.5 ng/ml), II (n=5, 21.9±8.5), III plus IV (n=8, 33.3±8.6), and control subjects (n=7, 14.0±4.6). Significant differences were found between patients with NYHA III plus IV and control subjects, but not between patients with NYHA I or II and control subjects.](image1)

![Relation between serum TRX levels and left ventricular ejection fractions (LVEF). The serum TRX levels were inversely correlated with LVEF (r=0.59, p=0.0002) in all the subjects. Dotted lines indicate ±95% reliability zone.](image2)
p<0.01 was considered statistically significant. Pearson’s rank correlation test was used to assess the relation between ejection fraction (EF) and TRX.

Results

No statistical significant difference in age among patients with DCM, ACS, EA or VSA, and control subjects was observed. The serum TRX levels did not correlate with age, sex, smoking, total cholesterol concentration, the presence of hypertension, or diabetes. The distribution of NYHA functional class in each group is shown in the Table 1. The serum TRX levels (mean±SD, ng/ml) were significantly higher in patients with DCM (n=5, 36.9±8.6) (p<0.001) and ACS (n=7, 30.6±4.9) (p<0.001) than in control subjects (n=7, 14.0±4.6).

We analyzed the association between the severity of NYHA functional class and the serum TRX levels in the control subjects and the patients (Fig 1) and found that the serum level of the patients with NYHA III and IV (n=8, 33.3±8.6) was significantly higher than in control subjects (p<0.01). The serum TRX levels of the patients with NYHA I (n=17, 19.1±8.5) and II (n=5, 21.9±8.5) were higher than in control subjects, but the differences were not significant (p=0.13 and p=0.08, respectively). In addition, the serum TRX levels inversely correlated with LVEF (Fig 2).

Discussion

The present study provides the first clinical evidence that serum TRX levels are associated with the NYHA functional class; that is, the serum TRX levels were elevated in patients with ACS and DCM compared with control subjects, and the levels negatively correlated with EF. The present results indicate a possible association between TRX and the severity of heart failure.

There is a definitive correlation between oxidative stress and ventricular dysfunction, and ventricular remodeling and progressive dilatation leading to end stage heart failure may be mediated by oxygen-derived free radicals. There is an increase in lipid peroxides in the blood of patients with congestive heart failure, and a significant negative correlation with LVEF ROS may exacerbate ischemia-induced injury by promoting unfavorable oxidative changes in membrane lipids and ion pumps, which causes reperfusion-induced arrhythmia. In heart failure, myocardial contractility is impaired by pressure or volume overload, which may cause a relative myocardial ischemia that in turn generates ROS. Moreover, decreased scavenging enzyme activity increases the generation of ROS and the compensatory mechanism of an increase in catecholamines enzyme activity increases the generation of ROS and the turn generates ROS.1,9 Moreover, decreased scavenging which may cause a relative myocardial ischemia that in contractility is impaired by pressure or volume overload, in membrane lipids and ion pumps, which causes reperfusion-induced injury by promoting unfavorable oxidative changes in membrane lipids and ion pumps, which causes reperfusion-induced arrhythmia. In heart failure, myocardial contractility is impaired by pressure or volume overload, which may cause a relative myocardial ischemia that in turn generates ROS. Moreover, decreased scavenging enzyme activity increases the generation of ROS and the compensatory mechanism of an increase in catecholamines enzyme activity increases the generation of ROS and the turn generates ROS. Therefore, it is likely that ROS are involved not only in the pathogenesis, but also in the active progression of congestive heart failure.

TRX is a small, ubiquitous protein with 2 redox-active half-cystein residues in the active center, and it has a cyto-

protective effect against oxidation via its redox-active property. TRX has been reported to scavenge hydrogen peroxide directly and it also regulates the cytotoxic activity of tumor necrosis factor. TRX and TRX mRNA are enhanced in the endothelial cells and macrophages of human atherosclerotic plaques, and TRX expression increases in balloon-injured rat arteries. TRX expression is upregulated during the acute stage in rats with giant cell myocarditis, and the development of acute immune-mediated myocarditis may be regulated by the cellular redox state via TRX. Recombinant TRX protected against reperfusion injury in an ischemic lung model and against reperfusion-induced arrhythmias in an isolated rat heart model and overexpression of TRX in transgenic mice attenuated focal ischemic brain damage. Taken together, these data indicate that TRX protects organs from the cytotoxicity caused by ROS.

Antioxidants, such as SOD and catalase, are reportedly decreased in patients with heart failure but in the present study, the serum TRX levels in patients with NYHA functional class III or IV, were significantly elevated. We postulate that the increase in the serum concentration of TRX may indirectly reflect the excessive oxidative stress caused by ROS associated with uncontrolled heart failure. Although further studies are necessary, especially on the origin of TRX, it may at present time be concluded that TRX plays a significant pathophysiological role in patients with heart failure.
