Abstract

Two kinds of iron oxide particles -spherical cobalt-containing iron oxide particles with spinel structure and platelet \(\gamma\)-Fe\(_2\)O\(_3\) particles- were synthesized for medical applications. The particle size of the spherical cobalt-containing iron oxide particles was about 20 nm regardless of the coercive force that was varied in the range of about 4.0 to 39.0 kA/m by varying the Co content. The size and coercive forces of the platelet \(\gamma\)-Fe\(_2\)O\(_3\) particles were in the range of about 30 to 100 nm and about 7.6 to 13.5 kA/m, respectively. The temperature-raising properties were evaluated for water dispersion of these particles under different AC magnetic fields and frequencies to apply hyperthermia or thermoablation using hysteresis-loss heating of ferrimagnetic particles. Heat generation in spherical cobalt-containing iron oxide particles was based on both hysteresis-loss and Brownian relaxation. Platelet \(\gamma\)-Fe\(_2\)O\(_3\) particles showed heat generation completely based on hysteresis-loss.

Key Words: Platelet \(\gamma\)-Fe\(_2\)O\(_3\), \(\alpha\)-FeOOH, Coercive force, Hyperthermia, Specific loss power

I. INTRODUCTION

Magnetic hyperthermia or thermoablation using small magnetic particles is a new approach for the non-surgical application of heat to cancerous tumors. Much related research has been carried out using magnetic fluids consisting of superparamagnetic iron oxide particles [1-3]. Hysteresis-loss heating with fine ferromagnetic or ferrimagnetic particles is not constrained by requirements such as accurate particle size or driving frequency, which are essential parameters in case of magnetic fluids consisting of superparamagnetic iron oxide particles [4]. To use hysteresis-loss, it is essential to apply a high magnetic field equivalent to that applied in superparamagnetic relaxation systems. There are few reports on hyperthermia or thermoablation that study the application of the hysteresis-loss heating of ferromagnetic or ferrimagnetic particles [5-7].

We prepared spinel-structured spherical cobalt-containing iron oxide particles that have a size of around 20 nm [8, 9] and platelet \(\gamma\)-Fe\(_2\)O\(_3\) particles that have a size of less than 100 nm [10] for medical applications. In this paper, we report the synthesis and characterization of these particles with different coercive forces and particle sizes. The mechanism of heat generation in these particles was discussed on the basis of the dependency of specific loss power (SLP) on magnetic field and frequency to apply the particles for hyperthermia or thermoablation using hysteresis-loss heating.

II. EXPERIMENTAL PROCEDURES

A. Synthesis of Spherical Cobalt-Containing Iron Oxide and Platelet \(\gamma\)-Fe\(_2\)O\(_3\) Particles

Cobalt-containing iron oxide particles with spinel structure were prepared by co-precipitation of Co\(^{2+}\), Fe\(^{2+}\), and Fe\(^{3+}\) ions in alkaline solutions. The solution of the metal ions was mixed by stirring with an NH\(_3\) solution. The precipitate was then hydrothermally treated at 130 °C for 2 h using an autoclave to grow spherical particles with the composition of Co\(_x\)Fe\(_{3-x}\)O\(_4\). The coercive forces of particles were adjusted by varying the Co content.

Platelet \(\gamma\)-Fe\(_2\)O\(_3\) particles were prepared as follows [11]: Fe\(^{3+}\) ions were precipitated in an alkaline solution containing sodium hydroxide and ethanolamine, following which it was hydrothermally treated at 130–180 °C for 2 h to grow \(\alpha\)-FeOOH particles. Ethanolamine was added to control the crystal growth of the \(\alpha\)-FeOOH particles. The size of \(\alpha\)-FeOOH particles was mainly controlled by changing the precipitation temperature in the range of about 5 °C to −3 °C. After the \(\alpha\)-FeOOH particles were coated with SiO\(_2\) to prevent sintering during thermal treatment, the \(\alpha\)-FeOOH particles were converted to \(\gamma\)-Fe\(_2\)O\(_3\) through dehydration in air, reduction in H\(_2\) gas, and subsequent oxidation in air. To examine the temperature-raising properties, water dispersions of these particles were prepared with a silane coupling agent as a dispersant using a sonicator.

March, 2014
B. Measurements

The shapes of the spherical cobalt-containing iron oxide, platelet α-FeOOH and platelet γ-Fe2O3 particles were observed using TEM. The coercive force (Hc) and the saturation magnetization (Ms) were measured for dried particle samples using a vibrating sample magnetometer (VSM) under a maximum magnetic field of 1035 kA/m.

The temperature-raising properties of the particles were examined using the water dispersions, by using a high-frequency magnetic field applicator and by changing the frequencies in the range of 117 to 429 kHz at the peak magnetic fields of 39.8 kA/m. Temperature increase versus time was recorded with a fiber-optic thermometer, at intervals of 1 s. For liquid dispersion samples, SLP, \( Q_F \), was estimated by using equation (1):

\[
\Delta T/t\Delta (m_F C_F + m_W C_W) = m_F Q_F
\]

where \( \Delta T/t\Delta \), \( m \), and \( C \) denote the ratio of increase in temperature, mass, and unit mass heat capacity, respectively. Suffixes \( F \) and \( W \) denote a ferromagnetic material part and water, respectively. The SLP was obtained from the maximum value of \( \Delta T/t\Delta \) [10].

III. RESULTS and DISCUSSION

A. Shape and Magnetic Properties of Spherical Cobalt-Containing Iron Oxide and Platelet γ-Fe2O3 Particles

Fig. 1 shows the TEM photograph of spherical cobalt-containing iron oxide particles with Hc of about 23.9 kA/m. The particle size was about 20 nm and was nearly constant regardless of Hc in the range of 4.0 to 39.0 kA/m. XRD showed the particles to be spinel-structured Fe3O4. Fig. 2 shows the relationship between the Co content and Hc of the particles. There was a linear relationship between the Co content and Hc. This means that the Hc can be controlled by adjusting the Co content. The Ms of the particles was in the range of about 76 to 80 Am²/kg for the Co content of 2 to 7 at%.

Figs. 3(a)–(c) show TEM photographs of α-FeOOH particles synthesized at different precipitation temperatures of 4.8 to −3.3 °C. The size of α-FeOOH was reduced on lowering the precipitation temperature and was more affected by the precipitation temperature than by the hydrothermal treating temperature and time.
Figs. 4(a)–(c) show TEM photographs of the γ-Fe2O3 particles obtained from the α-FeOOH particles shown in Figs. 3(a)–(c), respectively. Dimples formed in the dehydration process were clearly observed in γ-Fe2O3 particles, although they maintained the external form of α-FeOOH particles. Fig. 5 shows the relationship between the Hc and Ms of the γ-Fe2O3 particles having different particle sizes. The Hc of the γ-Fe2O3 particles was in the range of 7.6 to 13.5 kA/m, and decreased with their sizes.

**Fig. 5** Relationship between coercive force and saturation magnetization in γ-Fe2O3 particles having different particle sizes.

### B. Temperature-Raising Properties and Specific Loss Power

Temperature-raising properties were evaluated by measuring the rate of increase of temperature of water dispersions containing 0.90 wt% of platelet γ-Fe2O3 particles. Fig. 6 shows the temperature-raising properties measured for the water dispersion of γ-Fe2O3 particles with the Hc of 12.2 kA/m and an Ms of 56.6 Am2/g at the frequency range of 125 to 429 kHz under a peak magnetic field of 39.8 kA/m.

Fig. 7 shows the SLP plotted as a function of the product fH₀ of frequency and magnetic field based on the temperature-raising property shown in Fig. 6. The SLP was compared with those of spherical cobalt-containing iron oxide particles with the Hc of 11.9 kA/m. The SLP in the spherical cobalt-containing iron oxide particles showed the tendency to saturate at the product of frequency and magnetic field of about 8000 Hz·MA/m. This suggested that the heat generation in the spherical cobalt-contained iron oxide particles was based not only on the hysteresis-loss but the Brownian relaxation. The SLP in the platelet γ-Fe2O3 particles linearly increased with increasing fH₀. This showed that the heat generation in the platelet γ-Fe2O3 particles was completely based on the hysteresis-loss.

IV. CONCLUSIONS

Spherical cobalt-containing iron oxide particles and platelet $\gamma$-Fe$_2$O$_3$ particles with different coercive forces and particle sizes were synthesized for application in magnetic hyperthermia or thermoablation using hysteresis-loss heating of ferrimagnetic particles. Specific loss power was obtained from temperature-raising properties of water dispersions of these particles under different frequencies. Heat generation in spherical cobalt-containing iron oxide particles was based on both hysteresis-loss and Brown relaxation. Platelet $\gamma$-Fe$_2$O$_3$ particles showed heat generation completely based on hysteresis-loss.
