ESTIMATION OF VARIANCE AND COVARIANCE COMPONENTS IN ELLIPTICALLY CONTOURED DISTRIBUTIONS

Tatsuya Kubokawa*

This paper considers the problems of estimating the univariate and multivariate components of variance in *elliptically contoured distribution (ECD) models* in a decision-theoretic setup. Empirical Bayes or generalized Bayes estimators and several other positive or non-negative (definite) estimators, superior to usual ANOVA (unbiased) estimators of the variance components, are obtained. The robustness of the dominance results is investigated, and it is shown that all dominance results under normal models remain true within a specific class of distributions.

Key Words and Phrases: elliptically contoured distribution, robustness of improvement, variance components model, mixed linear regression model, statistical decision theory, point estimation.

1. Introduction

The estimation of variance components in univariate mixed linear models has been considered extensively in the literature and several results are available. Rao and Kleffe (1988) provide an exhaustive account of Rao's MINQUE theory. Other important contributions are due to Thompson (1962), Patterson and Thompson (1971, 1975), Searle (1971) and Harville (1977) who considered maximum likelihood and restricted maximum likelihood methods. However, since unbiased estimators of 'between' components of variance take negative values with positive probability, considerable attention has also been paid to provide positive estimators for 'between' components. Nonnegative estimators improving upon the unbiased estimators have also been derived by Mathew, Sinha and Sutradhar (1992), Kubokawa (1995) and Kubokawa, Saleh and Konno (2000) from a frequentist-view point. Recently, Srivastava and Kubokawa (1999) succeeded in extending the dominance results to estimation of covariance components in a multivariate mixed linear model with equal replications.

The dominance results in estimation of the variance components are essentially equivalent to those in estimation of ordered scale parameters and are related to the result of Stein (1964), who constructed a truncated procedure improving upon an unbiased estimator for a variance of a normal distribution with an unknown mean. These estimation issues are technically characterized to be resolved without employing the integration-by-parts methods, namely, the Stein and Haff identities, which are heavily employed to construct improved procedures in estimation of a mean vector and a covariance matrix of a

multivariate normal distribution. Recently, Kubokawa and Srivastava (1999, 2000) extended these identities to an elliptically contoured distribution model, and showed that almost all dominance results in the normal model remain true in the elliptically contoured distribution model by utilizing the extended identities. Then, one will have the query of whether such robustness of improvement holds for the estimation of the variance components in which the identities are of no use.

In this paper, we consider the problem of estimating the variance components σ_1^2 , σ_A^2 and their function $\sigma_2^2 = \sigma_1^2 + r\sigma_A^2$, and of estimating multivariate components of covariance in *elliptically contoured distribution models*, hereafter referred to as *ECD models*, in a decision-theoretic setup. Empirical Bayes or generalized Bayes estimators and several other positive or nonnegative (definite) estimators improving upon usual unbiased estimators of the variance components are obtained. These dominance results are discussed here in the ECD models from two aspects of parametric and semiparametric situations, which correspond to the cases where the function $f(\cdot)$ describing the ECD model is known and unknown, respectively. In the parametric case, it is shown that the structure of the dominance results still holds in the ECD models. In the semiparametric case, however, the superiority of improved estimators in the normal distribution does not hold for every unknown function $f(\cdot)$. When the ECD model are restricted to the class of multivariate t -distributions, the dominance results in estimation of σ_1^2 remain true, that is, the robust improvements are guaranteed while the robustness of the dominance never holds for estimation of σ_2^2 . This phenomenon demonstrates that two estimation issues of σ_1^2 and σ_2^2 with $\sigma_1^2 \leq \sigma_2^2$ possess different stories from the respect of the robust improvement. It is of great interest to point out that there exists a class of distributions in which the dominance results in the normal distribution remain true. Denote a class of the following distributions by C_0 :

$$C_0 = \left\{ f: f(\|x\|^2) = \frac{\nu^{\nu/2+1} \Gamma((N+\nu)/2+1)}{\pi^{N/2} \Gamma(\nu/2+1)} (\nu + \|x\|^2)^{-(N+\nu)/2+1}, \nu > 0 \right\},$$

which is slightly different from the multivariate t -distributions. Within this class, the robustness of the superiority of all estimators given in the normal model is established.

Section 2 deals with the estimation of the variance components in a one-way random effects model, which is represented in the ECD model with covariance having the intraclass correlation structure. In Subsection 2.2, broad classes of estimators improving on ANOVA (unbiased) estimators of the variance components are derived. Out of these classes, empirical Bayes and generalized Bayes rules are developed. These are extensions of results in Kubokawa *et al.* (2000) to the ECD model. In Subsection 2.3, we discuss the robustness of the dominance results given under the normality, and provide the class C_0 in which the results of Kubokawa *et al.* (2000) hold still for any $f(\cdot) \in C_0$. An extension to general mixed linear models with two variance components is shown in Subsection 2.4.

Section 3 is devoted to the estimation of multivariate components of variance in an ECD model which corresponds to a one-way multivariate mixed linear model with equal replications. This issue did not receive a much attention primarily due to technical difficulties encountered obtaining dominance results. Amemiya (1985) proposed a restricted maximum likelihood (REML) estimator for the 'between' component but it is not known whether it is better than the usual unbiased estimator. Also see Calvin and Dykstra (1991) and Mathew, Niyogi and Sinha (1994). Recently Srivastava and Kubokawa (1999) succeeded in establishing a truncation rule for improving on non-truncated procedures. This rule was applied to show the superiority of REML estimators to unbiased ones as well as to derive truncated estimators dominating Stein type minimax estimators. In Section 3, we extend these dominance results to the ECD model and investigate their robustness.

2. Estimation of variance components in a random effect model

In this section, we treat an elliptically contoured distribution (ECD) model with covariance having the intraclass correlation structure, which is interpreted as an extension of a one-way random effect model in the normal distribution. In this model, we consider the problem of estimating the variance components from two aspects of decision theory and robustness.

2.1. A random effect model and its canonical form

Let us consider the following model with a covariance structure of intraclass correlation:

$$(2.1) \quad \mathbf{y} = \mu \mathbf{j}_N + \mathbf{u},$$

where $\mathbf{y}$ is an $N \times 1$ observed vector, $\mu \in \mathbf{R}$ is an unknown common mean, $\mathbf{j}_N = (1, \dots, 1)^t \in \mathbf{R}^N$, and $\mathbf{u}$ is an N -variate error vector. Assume that the error has an elliptical density

$$(2.2) \quad |\mathbf{\Omega}|^{-1/2} f(\mathbf{u}^t \mathbf{\Omega}^{-1} \mathbf{u}),$$

where $\mathbf{\Omega}$ is a $N \times N$ matrix with the intraclass correlation structure

$$(2.3) \quad \mathbf{\Omega} = \sigma_1^2 \mathbf{I}_N + \sigma_a^2 \mathbf{J}_r \otimes \mathbf{I}_k,$$

for $\mathbf{J}_r = \mathbf{j}_r \mathbf{j}_r^t$, $N = kr$ and $\otimes$ designates the Kronecker product defined by $\mathbf{A} \otimes \mathbf{B} = (a_{ij} \mathbf{B})$ for $\mathbf{A} = (a_{ij})$. In the case of a normal distribution, this corresponds to the one-way mixed linear model with two variance components:

$$\mathbf{u} = \mathbf{j}_r \otimes \boldsymbol{\alpha} + \boldsymbol{\varepsilon},$$

where $\boldsymbol{\alpha}$ and $\boldsymbol{\varepsilon}$ are independent random variables with $\boldsymbol{\alpha} \sim \mathcal{N}_k(\mathbf{0}, \sigma_a^2 \mathbf{I}_k)$ and $\boldsymbol{\varepsilon} \sim \mathcal{N}_N(\mathbf{0}, \sigma_1^2 \mathbf{I}_N)$.

For providing a canonical form, consider $N \times N$ orthogonal matrix $\mathbf{H} = (\mathbf{H}_1^t, \mathbf{H}_2^t)^t$ for $1 \times N$ vector $\mathbf{H}_1 = N^{-1/2} \mathbf{j}_N^t$ and $(N-1) \times N$ matrix $\mathbf{H}_2$ such that $\mathbf{H}_2 \mathbf{j}_N = \mathbf{0}$ and $\mathbf{H}_2 \mathbf{H}_2^t = \mathbf{I}_{N-1}$. Let $x_0 = \mathbf{H}_1 \mathbf{y}$ and $\mathbf{z} = \mathbf{H}_2 \mathbf{y}$. The joint density of $\mathbf{H} \mathbf{y} = (x_0, \mathbf{z}^t)^t$ is written by

$$|\boldsymbol{\Omega}|^{-1/2} f(D(x_0) + \mathbf{z}^t (\sigma_1^2 \mathbf{I}_{N-1} + \sigma_a^2 \mathbf{H}_2 \{ \mathbf{I}_r \otimes \mathbf{J}_k \} \mathbf{H}_2^t)^{-1} \mathbf{z}),$$

where $D(x_0) = (x_0 - \mu\sqrt{N})^2 / (\sigma_1^2 + r\sigma_a^2)$. It can be easily seen that $\mathbf{H}_2 \{ \mathbf{I}_r \otimes \mathbf{J}_k \} \mathbf{H}_2^t = r\mathbf{E}_2$ where $\mathbf{E}_2$ is an $(N-1) \times (N-1)$ idempotent matrix with $\text{rank}(\mathbf{E}_2) = k-1$. Letting $\mathbf{E}_1 = \mathbf{I}_{N-1} - \mathbf{E}_2$ with $\text{rank}(\mathbf{E}_1) = N-k$, we see that

$$\sigma_1^2 \mathbf{I}_{N-1} + \sigma_a^2 \mathbf{H}_2 \{ \mathbf{I}_r \otimes \mathbf{J}_k \} \mathbf{H}_2^t = \sigma_1^2 \mathbf{E}_1 + (\sigma_1^2 + r\sigma_a^2) \mathbf{E}_2.$$

Then the density of $\mathbf{z}$ is expressed by

$$(\sigma_1^2)^{-n_1/2} (\sigma_2^2)^{-n_2/2} g(\sigma_1^{-2} \mathbf{z}^t \mathbf{E}_1 \mathbf{z} + \sigma_2^{-2} \mathbf{z}^t \mathbf{E}_2 \mathbf{z}),$$

where $n_1 = N-k$, $n_2 = k-1$, $\sigma_2^2 = \sigma_1^2 + r\sigma_a^2$ and

$$(2.4) \quad g(a) = \int \sigma_2^{-1} f(D(x_0) + a) dx_0.$$

Here we can take variables $x_1, \dots, x_{n_1}$ such that $\mathbf{z}^t \mathbf{E}_1 \mathbf{z} = \sum_{i=1}^{n_1} x_i^2 = \|\mathbf{x}\|^2$ for $\mathbf{x} = (x_1, \dots, x_{n_1})^t$. Let us define S_1 by $S_1 = \mathbf{z}^t \mathbf{E}_1 \mathbf{z}$. We here make the transformation $(x_1, \dots, x_{n_1}) \rightarrow (s_1, \theta_1, \dots, \theta_{n_1-1})$ such that

$$\begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_{n_1-1} \\ x_{n_1} \end{pmatrix} = \sqrt{s_1} \cdot \begin{pmatrix} \cos \theta_1 \\ \sin \theta_1 \cos \theta_2 \\ \vdots \\ \sin \theta_1 \sin \theta_2 \cdots \cos \theta_{n_1-1} \\ \sin \theta_1 \sin \theta_2 \cdots \sin \theta_{n_1-1} \end{pmatrix},$$

where $0 \leq \theta_i \leq \pi$ for $i=1, \dots, n_1-2$, and $0 \leq \theta_{n_1-1} \leq 2\pi$. Since the Jacobian is given by

$$\left| \frac{\partial(x_1, \dots, x_{n_1})}{\partial(s_1, \theta_1, \dots, \theta_{n_1-1})} \right| = 2^{-1} s_1^{(n_1-2)/2} \sin^{n_1-2} \theta_1 \sin^{n_1-3} \theta_2 \cdots \sin \theta_{n_1-2},$$

the joint density of $(S_1, \theta_1, \dots, \theta_{n_1-1}, \mathbf{E}_2 \mathbf{z})$ is expressed as

$$(2.5) \quad h(\theta_1, \dots, \theta_{n_1-1}) \times c_{n_1} (\sigma_1^2)^{-n_1/2} (\sigma_2^2)^{-n_2/2} s_1^{n_1/2-1} g(\sigma_1^{-2} s_1 + \sigma_2^{-2} \mathbf{z}^t \mathbf{E}_2 \mathbf{z}),$$

where

$$(2.6) \quad c_{n_1} = \frac{\pi^{n_1/2}}{\Gamma(n_1/2)} = \prod_{i=1}^{n_1-1} B\left(\frac{1}{2}, \frac{n_1-i}{2}\right),$$

and

$$h(\theta_1, \dots, \theta_{n_1-1}) = \frac{1}{2} \prod_{i=1}^{n_1-1} \frac{\sin^{n_1-i-1} \theta_i}{B(1/2, (n_1-i)/2)},$$

which is a uniform distribution on the hypersphere. Hence the joint density of $(S_1, \mathbf{E}_2 \mathbf{z})$ is given by

$$(2.7) \quad c_{n_1} (\sigma_1^2)^{-n_1/2} (\sigma_2^2)^{-n_2/2} s_1^{n_1/2-1} g(\sigma_1^{-2} s_1 + \sigma_2^{-2} \mathbf{z}^t \mathbf{E}_2 \mathbf{z}).$$

Let $S_2 = \mathbf{z}^t \mathbf{E}_2 \mathbf{z}$, and the same arguments provide the joint density of (S_1, S_2) of

the form

$$(2.8) \quad c_{n_1} c_{n_2} (\sigma_1^2)^{-n_1/2} (\sigma_2^2)^{-n_2/2} s_1^{n_1/2-1} s_2^{n_2/2-1} g(\sigma_1^{-2} s_1 + \sigma_2^{-2} s_2).$$

Here it is noted that S_1 and S_2 are represented by

$$(2.9) \quad \begin{aligned} S_1 &= \mathbf{z}^t \mathbf{E}_1 \mathbf{z} = \mathbf{y}^t \mathbf{H}_2^t \mathbf{E}_1 \mathbf{H}_2 \mathbf{y} \\ &= \mathbf{y}^t \left(\mathbf{I}_{kr} - \frac{1}{r} \mathbf{I}_k \otimes \mathbf{J}_r \right) \mathbf{y} \\ &= \sum_{i=1}^k \sum_{j=1}^r (y_{ij} - \bar{y}_{i.})^2 \end{aligned}$$

and

$$(2.10) \quad \begin{aligned} S_2 &= \mathbf{z}^t \mathbf{E}_2 \mathbf{z} = \mathbf{y}^t \mathbf{H}_2^t \mathbf{E}_2 \mathbf{H}_2 \mathbf{y} \\ &= \mathbf{y}^t \left(\frac{1}{r} \mathbf{I}_k \otimes \mathbf{J}_r - \frac{1}{rk} \mathbf{J}_{rk} \right) \mathbf{y} \\ &= r \sum_{i=1}^k (\bar{y}_{i.} - \bar{y}_{..})^2, \end{aligned}$$

for $\bar{y}_{i.} = r^{-1} \sum_{j=1}^r y_{ij}$ and $\bar{y}_{..} = (rk)^{-1} \sum_{i=1}^k \sum_{j=1}^r y_{ij}$. The estimation of the variance components is discussed in the following subsections on the basis of the density (2.8).

2.2. Estimation of the variance components

Now we address the problems of estimating σ_1^2 , σ_2^2 and (σ_1^2, σ_2^2) based on the canonical form (2.8) of the ECD model (2.1). For each estimation problem, we provide generalized Bayes and empirical Bayes estimators improving upon ordinary procedures.

The estimation of the 'within' component of variance σ_1^2 is first discussed with respect to the Stein loss $L(\hat{\sigma}_1^2, \sigma_1^2)$, where the function $L(\cdot, \cdot)$ is defined by

$$(2.11) \quad L(a, b) = a/b - \log a/b - 1.$$

It is noted that the loss $L(\hat{\sigma}_1^2, \sigma_1^2)$ can be derived from the Kullback-Leibler information loss in the normal or chi-squared distributions. The unbiased estimator based on S_1 is given by

$$(2.12) \quad \hat{\sigma}_1^{2UB}(g) = n_1^{-1} S_1 (n_1 + n_2) A_{n_1+n_2}(g),$$

which is the best among multiples of S_1 where

$$(2.13) \quad A_k(g) = \frac{\int_0^\infty y^{k/2-1} g(y) dy}{\int_0^\infty y^{k/2} g(y) dy}.$$

In fact, the coefficient of S_1 in (2.12) is calculated from (2.8) as

$$\begin{aligned}
E[S_1] &= \sigma_1^2 \iint c_{n_1} c_{n_2} s_1^{n_1/2} s_2^{n_2/2-1} g(s_1 + s_2) ds_1 ds_2 \\
&= \sigma_1^2 c_{n_1} c_{n_2} \int_0^1 z^{n_1/2} (1-z)^{n_2/2-1} dz \times \int_0^\infty y^{(n_1+n_2)/2} g(y) dy \\
&= \frac{n_1}{n_1 + n_2} \frac{1}{A_{n_1+n_2}(g)},
\end{aligned}$$

where the transformation $(s_1, s_2) \rightarrow (yz, y(1-z))$ is made in the second equality, and the extreme equality follows from

$$(c_{n_1} c_{n_2})^{-1} = \int_0^1 z^{n_1/2-1} (1-z)^{n_2/2-1} dz \times \int_0^\infty y^{(n_1+n_2)/2-1} g(y) dy.$$

It is noted that the parameters σ_1^2 and σ_2^2 are restricted by the inequality $\sigma_1^2 \leq \sigma_2^2$, which implies that S_2 contains the information up to σ_1^2 . This information will be employed to improve upon the unbiased estimator $\hat{\sigma}_1^{2UB}(g)$. For the purpose, more generally, we consider the estimators of the form

$$(2.14) \quad \hat{\sigma}_1^2(\phi) = S_1 \phi(S_2/S_1)$$

and obtain the condition on $\phi(\cdot)$ for $\hat{\sigma}_1^2(\phi)$ dominating estimator $a_1 S_1$, a multiple of S_1 .

PROPOSITION 2.1. Assume that

- (a) $\phi(w)$ is nondecreasing and $\lim_{w \rightarrow \infty} \phi(w) = a_1$,
- (b) $\phi(w) \geq \phi_0(w) A_{n_1+n_2}(g)$ where

$$(2.15) \quad \phi_0(w) = \frac{\int_0^w x^{n_2/2-1} (1+x)^{-(n_1+n_2)/2} dx}{\int_0^w x^{n_2/2-1} (1+x)^{-(n_1+n_2)/2-1} dx}.$$

Then $S_1 \phi(S_2/S_1)$ is better than $a_1 S_1$ uniformly for every ω relative to the loss $L(\hat{\sigma}_1^2, \sigma_1^2)$ for $L(\cdot, \cdot)$ given by (2.11).

The proof is referred to Section 2.5. From Proposition 2.1, we can get some specific improved estimators of σ_1^2 , which will be given after stating the results corresponding to Proposition 2.1 for σ_2^2 . For the estimation of σ_2^2 , the unbiased estimator is given by

$$(2.16) \quad \hat{\sigma}_2^{2UB}(g) = n_2^{-1} S_2 (n_1 + n_2) A_{n_1+n_2}(g),$$

for $A_{n_1+n_2}(g)$ defined by (2.13). For improving upon the unbiased estimator or the multiple of S_2 , we consider estimators of the form

$$(2.17) \quad \hat{\sigma}_2^2(\phi) = S_2 \phi(S_1/S_2).$$

PROPOSITION 2.2. Assume that

- (a) $\phi(w)$ is nondecreasing and $\lim_{w \rightarrow 0} \phi(w) = a_2$,
- (b) $\phi(w) \leq \phi_0(w) A_{n_1+n_2}(g)$, where

$$(2.18) \quad \phi_0(w) = \frac{\int_0^{1/w} x^{n_2/2-1} (1+x)^{-(n_1+n_2)/2} dx}{\int_0^{1/w} x^{n_2/2} (1+x)^{-(n_1+n_2)/2-1} dx}.$$

Then $S_2\phi(S_1/S_2)$ is better than a_2S_2 uniformly for every ω relative to the loss $L(\hat{\sigma}_2^2, \sigma_2^2)$ for $L(\cdot, \cdot)$ given by (2.11).

The proof is given in Section 2.5. In Propositions 2.1 and 2.2, the difference between the normal and elliptically contoured distributions appears in $A_{n_1+n_2}(g)$. This means that the same techniques as used in the case of the normal distribution are helpful for providing specific forms of improved procedures. From Lemma 1 of Kubokawa *et al.* (2000), it follows that

(i) $\phi_0(w)$ is increasing, $\lim_{w \rightarrow \infty} \phi_0(w) = (n_1 + n_2)/n_1$ and $\phi_0(w) \leq 1 + n_2(n_2 + 2)^{-1}w$,
(ii) $\phi_0(w)$ is increasing, $\lim_{w \rightarrow 0} \phi_0(w) = (n_1 + n_2)/n_2$ and $\phi_0(w) \geq 1 + (n_2 + 2)n_2^{-1}w$.
Letting $\phi_1(w) = \min\{(n_1 + n_2)n_1^{-1}, 1 + w\}A_{n_1+n_2}(g)$ and $\phi_2(w) = \min\{(n_1 + n_2)n_1^{-1}, 1 + (n_2 + 2)n_2^{-1}w\}A_{n_1+n_2}(g)$, we see that $\phi_0(w)$, $\phi_1(w)$ and $\phi_2(w)$ satisfy the conditions (a) and (b) of Proposition 2.1 for $a_1 = n_1^{-1}(n_1 + n_2)A_{n_1+n_2}(g)$. Then we obtain the improved estimators

$$\begin{aligned} \hat{\sigma}_1^{2GB}(g) &= S_1\phi_0(S_2/S_1)A_{n_1+n_2}(g), \\ \hat{\sigma}_1^{2REML}(g) &= \min\left\{\frac{S_1}{n_1}, \frac{S_1 + S_2}{n_1 + n_2}\right\}(n_1 + n_2)A_{n_1+n_2}(g), \\ \hat{\sigma}_1^{2EB}(g) &= \min\left\{\frac{S_1}{n_1}, \frac{S_1 + n_2(n_2 + 2)^{-1}S_2}{n_1 + n_2}\right\}(n_1 + n_2)A_{n_1+n_2}(g). \end{aligned}$$

Similarly, combining Proposition 2.2 and the above arguments provides the estimators

$$\begin{aligned} \hat{\sigma}_2^{2GB}(g) &= S_2\phi_0(S_1/S_2)A_{n_1+n_2}(g), \\ \hat{\sigma}_2^{2REML}(g) &= \max\left\{\frac{S_2}{n_2}, \frac{S_1 + S_2}{n_1 + n_2}\right\}(n_1 + n_2)A_{n_1+n_2}(g), \\ \hat{\sigma}_2^{2EB}(g) &= \max\left\{\frac{S_2}{n_2}, \frac{(n_2 + 2)n_2^{-1}S_1 + S_2}{n_1 + n_2}\right\}(n_1 + n_2)A_{n_1+n_2}(g), \end{aligned}$$

having uniformly smaller risks than the unbiased one (2.16). The generalized Bayesness of $\hat{\sigma}_1^{2GB}$ and $\hat{\sigma}_2^{2GB}$ and the empirical Bayesness of $\hat{\sigma}_1^{2REML}$, $\hat{\sigma}_1^{2EB}$, $\hat{\sigma}_2^{2REML}$ and $\hat{\sigma}_2^{2EB}$ can be demonstrated in the end of this subsection. It is noted that $\hat{\sigma}_1^{2REML}$ and $\hat{\sigma}_2^{2REML}$ can be derived as the restricted maximum likelihood (REML) estimators in the case of the normal distribution.

We deal with the third issue of estimating the variance components (σ_1^2, σ_a^2) simultaneously relative to the intrinsic loss

$$(2.19) \quad L_s(\hat{\sigma}_1^2, \hat{\sigma}_a^2, \sigma_1^2, \sigma_a^2) = n_1L(\hat{\sigma}_1^2, \sigma_1^2) + n_2L(\hat{\sigma}_1^2 + r\hat{\sigma}_a^2, \sigma_1^2 + r\sigma_a^2),$$

where $L(\cdot, \cdot)$ is defined in (2.11). The ANOVA (unbiased) estimator of (σ_1^2, σ_a^2) is given by $(\hat{\sigma}_1^{2UB}, r^{-1}(\hat{\sigma}_2^{2UB} - \hat{\sigma}_1^{2UB}))$. This form suggests to consider the estimators of the form $(\hat{\sigma}_1^2(\phi), \hat{\sigma}_a^2(\phi, \psi))$ where $\hat{\sigma}_1^2(\phi) = S_1\phi(S_2/S_1)$ and $\hat{\sigma}_a^2(\phi, \psi)$

$= r^{-1}\{S_2\phi(S_1/S_2) - S_1\phi(S_2/S_1)\}$. Then the risk function of this estimator relative to the loss (2.19) is written by

$$(2.20) \quad R_s(\omega, \hat{\sigma}_1^2, \hat{\sigma}_a^2) = n_1 E[L(S_1\phi(S_2/S_1), \sigma_1^2)] + n_2 E[L(S_2\phi(S_1/S_2), \sigma_2^2)],$$

which implies that Propositions 2.1 and 2.2 can be directly applied to get specific estimators superior to $(\hat{\sigma}_1^{2UB}, \hat{\sigma}_a^{2UB})$. Especially for σ_a^2 , we obtain the improved estimators:

$$\begin{aligned} \hat{\sigma}_a^{2GB}(g) &= r^{-1}\{S_2\phi_0(S_1/S_2) - S_1\phi_0(S_2/S_1)\}A_{n_1+n_2}(g), \\ \hat{\sigma}_a^{2REML}(g) &= r^{-1} \max\left\{\frac{S_2}{n_2} - \frac{S_1}{n_1}, 0\right\}(n_1 + n_2)A_{n_1+n_2}(g), \\ \hat{\sigma}_a^{2EB}(g) &= r^{-1} \max\left\{\frac{n_1}{n_2} \frac{S_2}{S_1} - 1, \frac{2}{n_2}\right\} \\ &\quad \times \min\left\{\frac{S_1}{n_1}, \frac{S_1 + n_2(n_2 + 2)^{-1}S_2}{n_1 + n_2}\right\}(n_1 + n_2)A_{n_1+n_2}(g). \end{aligned}$$

It is noted that $\hat{\sigma}_a^{2REML}(g)$ is nonnegative and that $\hat{\sigma}_a^{2GB}(g)$ and $\hat{\sigma}_a^{2EB}(g)$ are positive almost everywhere. Although the unbiased estimator $\hat{\sigma}_a^{2UB}$ has a drawback of taking negative values with positive probability, the above improved estimators resolve this undesirable property.

We conclude this subsection with stating the Bayesian properties of the above given estimators.

Let $\eta = 1/\sigma_1^2$ and $\xi = \sigma_1^2/(\sigma_1^2 + r\sigma_a^2)$ and note that ξ is constrained by $0 < \xi < 1$. When prior distribution $\pi(\eta, \xi)$ of (η, ξ) is supposed, the Bayes estimators under the corresponding loss functions are generally given by $\hat{\sigma}_1^{2B}$, $\hat{\sigma}_2^{2B}$ and $(\hat{\sigma}_1^{2B}, \hat{\sigma}_a^{2B})$ where

$$\begin{aligned} \hat{\sigma}_1^{2B} &= \frac{1}{E^\pi[\eta | S_1, S_2]}, \\ \hat{\sigma}_2^{2B} &= \frac{1}{E^\pi[\eta\xi | S_1, S_2]}, \\ \hat{\sigma}_a^{2B} &= \frac{1}{r} \left[\frac{1}{E^\pi[\eta\xi | S_1, S_2]} - \hat{\sigma}_1^{2B} \right], \end{aligned}$$

where $E^\pi[\cdot | S_1, S_2]$ stands for an expectation with respect to the posterior distribution $\pi(\eta, \xi | S_1, S_2)$ of (η, ξ) given S_1 and S_2 .

For deriving the generalized Bayes estimators, suppose the improper prior distribution

$$\pi(\eta, \xi) d\eta d\xi = \eta^{-1} \xi^{-1} d\eta d\xi I(0 < \xi < 1),$$

for the indicator function $I(\cdot)$. Then the posterior density of (η, ξ) given S_1 and S_2 is proportional to

$$\xi^{n_2/2-1} \eta^{(n_1+n_2)/2-1} g((S_1 + \xi S_2)\eta) d\eta d\xi I(0 < \xi < 1).$$

By using this posterior distribution, it can be easily verified that the estimators $\hat{\sigma}_1^{2GB}(g)$, $\hat{\sigma}_2^{2GB}(g)$ and $\hat{\sigma}_a^{2GB}(g)$ are generalized Bayes.

For deriving the empirical Bayes estimators, let d be a given positive constant less than or equal to one, and suppose the improper prior distribution $\pi(\eta, \xi) = \eta^{-1} I(\xi = \xi_0)$ where $P(\xi = \xi_0) = 1$ and ξ_0 is an unknown constant such that $0 < \xi_0 \leq d$. Namely the supposed prior information about ξ is that ξ is unknown and in the interval $(0, d]$. Then the posterior density of η given S_1 and S_2 , and the marginal density of S_1 and S_2 are given by

$$\begin{aligned} (\text{posterior density}) &\propto \eta^{(n_1+n_2)/2-1} g((S_1 + \xi_0 S_2)\eta), \\ (\text{marginal density}) &\propto \xi_0^{n_2/2} [S_1 + \xi_0 S_2]^{-(n_1+n_2)/2} S_1^{n_1/2-1} S_2^{n_2/2-1} \\ &\quad \times \int_0^\infty y^{(n_1+n_2)/2-1} g(y) dy. \end{aligned}$$

Hence the Bayes estimators of σ_1^2 , σ_2^2 and σ_a^2 are

$$\begin{aligned} \hat{\sigma}_1^{2B}(\xi_0) &= (S_1 + \xi_0 S_2) A_{n_1+n_2}(g), \\ \hat{\sigma}_2^{2B}(\xi_0) &= (\xi_0)^{-1} (S_1 + \xi_0 S_2) A_{n_1+n_2}(g), \\ \hat{\sigma}_a^{2B}(\xi_0) &= \frac{1}{r} [\hat{\sigma}_2^{2B}(\xi_0) - \hat{\sigma}_1^{2B}(\xi_0)] \\ &= \frac{1 - \xi_0}{r \xi_0} (S_1 + \xi_0 S_2) A_{n_1+n_2}(g). \end{aligned}$$

Since ξ_0 is unknown, it should be estimated from the marginal density. Noting that $0 < \xi_0 < d$, it is seen that the maximum likelihood estimator of ξ_0 is written by $\hat{\xi}_0^{ML} = \min\{n_2 S_1 / (n_1 S_2), d\}$, which is substituted in the above Bayes estimators so as to obtain the empirical Bayes rules:

$$\begin{aligned} \hat{\sigma}_1^{2EB}(d) &= \hat{\sigma}_1^{2B}(\hat{\xi}_0^{ML}) \\ &= \min\left\{\frac{S_1}{n_1}, \frac{S_1 + d S_2}{n_1 + n_2}\right\} (n_1 + n_2) A_{n_1+n_2}(g), \\ \hat{\sigma}_2^{2EB}(d) &= \hat{\sigma}_2^{2B}(\hat{\xi}_0^{ML}) \\ &= \max\left\{\frac{S_2}{n_2}, \frac{S_1/d + S_2}{n_1 + n_2}\right\} (n_1 + n_2) A_{n_1+n_2}(g) \end{aligned}$$

and

$$\begin{aligned} \hat{\sigma}_a^{2EB}(d) &= \hat{\sigma}_a^{2B}(\hat{\xi}_0^{ML}) \\ &= \frac{1}{r} \max\left\{\frac{n_1}{n_2} \frac{S_2}{S_1} - 1, d^{-1} - 1\right\} \\ &\quad \times \min\left\{\frac{S_1}{n_1}, \frac{S_1 + d S_2}{n_1 + n_2}\right\} (n_1 + n_2) A_{n_1+n_2}(g). \end{aligned}$$

Especially putting $d=1$ yields the estimators $\hat{\sigma}_1^{2REML}(g)$, $\hat{\sigma}_2^{2REML}(g)$ and $\hat{\sigma}_a^{2REML}(g)$. Also putting $d = n_2 / (n_2 + 2)$ gives $\hat{\sigma}_1^{2EB}(g)$, $\hat{\sigma}_2^{2EB}(g)$ and $\hat{\sigma}_a^{2EB}(g)$.

2.3. Robustness of the improvements

The results given in the previous subsection depend on the function g or f through $A_{n_1+n_2}(g)$. Especially for the normal distribution, the corresponding conclusions are provided by letting $A_{n_1+n_2}(g) = (n_1 + n_2)^{-1}$. For instance, the unbiased estimators of σ_1^2 , σ_2^2 and σ_a^2 are given by $\hat{\sigma}_1^{2UB} = n_1^{-1} S_1$, $\hat{\sigma}_2^{2UB} = n_2^{-1} S_2$ and

$\hat{\sigma}_a^{2UB} = r^{-1}(\hat{\sigma}_2^{2UB} - \hat{\sigma}_1^{2UB})$, which are improved by several truncated and smooth procedures.

The objective in this subsection is to investigate whether these improvements are robust within a class of functions f . The conditions for the robust improvements on $\hat{\sigma}_1^{2UB} = n_1^{-1}S_1$ and $\hat{\sigma}_2^{2UB} = n_2^{-1}S_2$ can be derived based on Propositions 2.1 and 2.2. Let C be a class of functions on nonnegative real numbers.

PROPOSITION 2.3. Assume that

(a) $\phi(w)$ is nondecreasing and $\lim_{w \rightarrow \infty} \phi(w) = n_1^{-1}$,

(b) $\phi(w) \geq \phi_0(w) \sup_{g \in C} A_{n_1+n_2}(g)$.

Then $S_1\phi(S_2/S_1)$ is better than $n_1^{-1}S_1$ uniformly for every ω and every $g \in C$.

PROPOSITION 2.4. Assume that

(a) $\phi(w)$ is nondecreasing and $\lim_{w \rightarrow 0} \phi(w) = n_2^{-1}$,

(b) $\phi(w) \leq \phi_0(w) \inf_{g \in C} A_{n_1+n_2}(g)$.

Then $S_2\phi(S_1/S_2)$ is better than $n_2^{-1}S_2$ uniformly for every ω and every $g \in C$.

Proposition 2.3 and 2.4 imply that the robustness of improvement in estimation of σ_1^2 has a quite different story from the case of estimation of σ_2^2 : the robust improvements for σ_1^2 hold in the case where $\sup_{g \in C} A_{n_1+n_2}(g) \leq (n_1+n_2)^{-1}$, while those for σ_2^2 hold when $\inf_{g \in C} A_{n_1+n_2}(g) \geq (n_1+n_2)^{-1}$. This further means that the robustness of improvements in estimation of (σ_1^2, σ_a^2) are guaranteed in the only case where $A_{n_1+n_2}(g) = (n_1+n_2)^{-1}$ for all g in C .

The underlying distributions are hereafter focused on a class of normal-scale-mixed distributions:

$$(2.21) \quad f_H(\|\mathbf{x}\|^2) = \int_0^\infty (2\pi)^{-N/2} \eta^{N/2} e^{-(\eta/2)\|\mathbf{x}\|^2} dH(\eta),$$

where $\mathbf{x} \in \mathbf{R}^N$ and $H(\cdot)$ is a probability measure on nonnegative real numbers. Then g defined in (2.4) is expressed by

$$(2.22) \quad g_H(y) = \int_0^\infty (2\pi)^{(n_1+n_2)/2} \eta^{(n_1+n_2)/2} e^{-\eta y/2} dH(\eta),$$

where $N-1 = n_1 + n_2$. Also $A_{n_1+n_2}(g)$ defined in (2.13) is written as

$$\begin{aligned} A_{n_1+n_2}(g_H) &= \frac{\int_0^\infty y^{(n_1+n_2)/2-1} \int_0^\infty \eta^{(n_1+n_2)/2} e^{-\eta y/2} dH(\eta) dy}{\int_0^\infty y^{(n_1+n_2)/2} \int_0^\infty \eta^{(n_1+n_2)/2} e^{-\eta y/2} dH(\eta) dy} \\ &= (n_1+n_2)^{-1} \cdot \frac{\int_0^\infty dH(\eta)}{\int_0^\infty \eta^{-1} dH(\eta)} \\ &= (n_1+n_2)^{-1} \cdot \left[\int_0^\infty \eta^{-1} dH(\eta) \right]^{-1}, \end{aligned}$$

which implies that

$A_{n_1+n_2}(g) \leq (\text{resp. } >) (n_1+n_2)^{-1}$ if and only if $\int_0^\infty \eta^{-1} dH(\eta) \geq (\text{resp. } <) 1$.

The normal distribution corresponds to taking the probability as $H(\{\eta=1\})=1$.

Let us specify the density $h(\eta)=dH(\eta)/d\eta$ as

$$(2.23) \quad h(\eta) = \frac{1}{\Gamma(a/2)} \left(\frac{b}{2}\right)^{a/2} \eta^{a/2-1} e^{-b\eta/2} I(\eta > 0),$$

for $a > 2$ and $b > 0$. Then

$$\int_0^\infty \eta^{-1} dH(\eta) = \frac{b}{a-2}.$$

We thus consider the following three classes.

(i) Putting $a=\nu+2$ and $b=\nu$ in (2.23) for $\nu > 0$ gives that $\int_0^\infty \eta^{-1} dH(\eta) = 1$ and produces a class of densities of the form

$$(2.24) \quad C_0 = \left\{ f: f(\|\mathbf{x}\|^2) = \frac{\nu^{\nu/2+1} \Gamma((N+\nu)/2+1)}{\pi^{N/2} \Gamma(\nu/2+1)} (\nu + \|\mathbf{x}\|^2)^{-(N+\nu)/2+1}, \nu > 0 \right\}.$$

This includes the normal distribution as a limit of ν . Since $A_{n_1+n_2}(g) = (n_1 + n_2)^{-1}$ for all $f \in C_0$, all dominance results in the three estimation issues in the normal distribution remain true in C_0 . Especially the robustness of improvements is guaranteed for the simultaneous estimation of (σ_1^2, σ_a^2) .

(ii) Putting $a=b=\nu$ in (2.23) for $\nu > 2$ gives that $\int_0^\infty \eta^{-1} dH(\eta) = \nu/(\nu-2) > 1$ and produces a class of multivariate t -distributions, where the density is of the form

$$(2.25) \quad C_1 = \left\{ f: f(\|\mathbf{x}\|^2) = \frac{\nu^{\nu/2} \Gamma((N+\nu)/2)}{\pi^{N/2} \Gamma(\nu/2)} (\nu + \|\mathbf{x}\|^2)^{-(N+\nu)/2}, \nu > 0 \right\}.$$

The robust improvements still hold for σ_1^2 while they are not guaranteed for σ_2^2 . When we can impose the restriction on ν as $\nu \geq \nu_0$ for known value $\nu_0 > 2$, from Proposition 3.4, it follows that $\hat{\sigma}_2^{2UB}$ is dominated by $\max\{n_1^{-1}S_1, \nu_0^{-1}(\nu_0-2)(n_1 + n_2)^{-1}(S_1 + S_2)\}$ uniformly within the class C_1 with $\nu \geq \nu_0$.

(iii) In the case that $a=\nu+4$ and $b=\nu$ for $\nu > 0$, we observe that $\int_0^\infty \eta^{-1} dH(\eta) = \nu/(\nu+2) < 1$, so that the robust improvements are guaranteed for σ_2^2 while they never hold for σ_1^2 .

As stated in (i), it is quite interesting to point out again that Propositions 2.1 and 2.2 with $A_{n_1+n_2}(g) = (n_1 + n_2)^{-1}$ remain still established for all f in C_0 , that is, the robustness of all dominance results in the normal distribution holds.

As one of other classes, we can consider contaminated normal distributions such that the error term $\mathbf{u}$ in the model (2.1) has

$$(2.26) \quad (1-\lambda)\mathcal{N}_N(\mathbf{0}, \mathbf{\Omega}) + \lambda\mathcal{N}_N(\mathbf{0}, \tau\mathbf{\Omega}),$$

where λ and τ are unknown parameters satisfying $0 < \lambda < 1$ and $\tau > 1$. This model means some data with a larger variance can be taken with probability λ . Since this distribution is derived by putting $H(\{\eta=1\}) = \lambda$ and $H(\{\eta=\tau\}) = 1-\lambda$, we see that

$$\int_0^\infty \eta^{-1} dH(\eta) = \lambda + \tau^{-1}(1-\lambda) < 1,$$

which implies the robustness of improvements in the estimation of σ_1^2 .

2.4. An extension to general mixed linear models

We extend the results of the previous subsections to the following models with a more general covariance structure:

$$(2.27) \quad \mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \mathbf{u},$$

where $\mathbf{y}$ is an $N \times 1$ vector of observations, $\mathbf{X}$ is an $N \times p_1$ known matrix with $\text{rank}(\mathbf{X}) = r$, $\boldsymbol{\beta}$ is a $p_1 \times 1$ vector of parameters and $\mathbf{u}$ is an N -variate random error vector having the elliptical density (2.2) with

$$(2.28) \quad \boldsymbol{\Omega} = \sigma_1^2 \mathbf{I}_N + \sigma_a^2 \mathbf{A} \mathbf{A}^t,$$

for $N \times p_2$ known matrix $\mathbf{A}$. In the case of a normal distribution, this corresponds to the general mixed linear model with two variance components:

$$\mathbf{u} = \mathbf{A}\boldsymbol{\alpha} + \boldsymbol{\varepsilon},$$

where $\boldsymbol{\alpha}$ and $\boldsymbol{\varepsilon}$ are independent random variables with $\boldsymbol{\alpha} \sim \mathcal{N}_{p_2}(\mathbf{0}, \sigma_a^2 \mathbf{I}_{p_2})$ and $\boldsymbol{\varepsilon} \sim \mathcal{N}_N(\mathbf{0}, \sigma_1^2 \mathbf{I}_N)$. This includes a one-way random effects model with unbalanced replications and an error component model treated in Fuller and Battese (1973), Battese *et al.* (1988) and Rao *et al.* (1993).

For giving a canonical form, consider $N \times N$ orthogonal matrix $\mathbf{H}^* = (\mathbf{H}_1^{*t}, \mathbf{H}_2^{*t})^t$ such that $\mathbf{H}_2^* \mathbf{X} = \mathbf{0}$, $\mathbf{H}_2^* \mathbf{H}_2^{*t} = \mathbf{I}_{N-r}$ and $\mathbf{H}_2^*$ is an $(N-r) \times N$ matrix. Let $\mathbf{x}_0 = \mathbf{H}_1^* \mathbf{y}$ and $\mathbf{z} = \mathbf{H}_2^* \mathbf{y}$. Define $\boldsymbol{\Omega}^*$ by

$$\begin{aligned} \boldsymbol{\Omega}^* &= \begin{pmatrix} \boldsymbol{\Omega}_{11}^* & \boldsymbol{\Omega}_{12}^* \\ \boldsymbol{\Omega}_{21}^* & \boldsymbol{\Omega}_{22}^* \end{pmatrix} \\ &= \sigma_1^2 \mathbf{I}_N + \sigma_a^2 \mathbf{H}^* \mathbf{A} \mathbf{A}^t \mathbf{H}^{*t}, \end{aligned}$$

for $r \times r$ matrix $\boldsymbol{\Omega}_{11}^*$. Then the marginal density of $\mathbf{z}$ is written by $|\boldsymbol{\Omega}_{22}^*|^{-1/2} g(\mathbf{z}^t \boldsymbol{\Omega}_{22}^{*-1} \mathbf{z})$ where

$$(2.29) \quad g(a) = \int |\boldsymbol{\Omega}_{11.2}^*|^{-1/2} f(D(\mathbf{x}_0) + a) d\mathbf{x}_0,$$

for $\boldsymbol{\Omega}_{11.2}^* = \boldsymbol{\Omega}_{11}^* - \boldsymbol{\Omega}_{12}^* \boldsymbol{\Omega}_{22}^{*-1} \boldsymbol{\Omega}_{21}^*$ and

$$D(\mathbf{x}_0) = (\mathbf{x}_0 - \mathbf{H}_1^* \mathbf{X} \boldsymbol{\beta} - \boldsymbol{\Omega}_{12}^* \boldsymbol{\Omega}_{22}^{*-1})^t \boldsymbol{\Omega}_{11.2}^{*-1} (\mathbf{x}_0 - \mathbf{H}_1^* \mathbf{X} \boldsymbol{\beta} - \boldsymbol{\Omega}_{12}^* \boldsymbol{\Omega}_{22}^{*-1}).$$

Here we consider the spectral decomposition $\mathbf{H}_2^* \mathbf{A} \mathbf{A}^t \mathbf{H}_2^{*t} = \sum_{i=1}^{\ell} \lambda_i \mathbf{E}_i$, where $\text{rank}(\mathbf{E}_i) = m_i$ and $\sum_{i=1}^{\ell} m_i = \text{rank}(\mathbf{H}^* \mathbf{U} \mathbf{U}^t \mathbf{H}^{*t})$. Assume that $N - r - \sum_{i=1}^{\ell} m_i > 0$, and let

$$(2.30) \quad n_1 = N - r - \sum_{i=1}^{\ell} m_i \quad \text{and} \quad n_2 = \sum_{i=1}^{\ell} m_i.$$

Let $\mathbf{E}_0 = \mathbf{I}_{N-r} - \sum_{i=1}^{\ell} \mathbf{E}_i$, whose rank is n_1 . We thus get the quadratic statistics $S_1 = \mathbf{z}^t \mathbf{E}_0 \mathbf{z}$ and $T_i = \mathbf{z}^t \mathbf{E}_i \mathbf{z}$ for $i = 1, \dots, \ell$. The same argument as used above (2.5) gives a joint density of $(S_1, T_1, \dots, T_{\ell})$ of the form

$$(2.31) \quad c_{n_1}(\sigma_1^2)^{-n_1/2} S_1^{n_1/2-1} \prod_{i=1}^{\ell} \{c_{m_i}(\sigma_1^2 + \lambda_i \sigma_a^2)^{-m_i/2} t_i^{m_i/2-1}\} \\ \times g\left(\sigma_1^{-2} S_1 + \sum_{i=1}^{\ell} (\sigma_1^2 + \lambda_i \sigma_a^2)^{-1} t_i\right),$$

where the constant c_{n_1} is defined by (2.6) and c_{m_i} 's are defined similarly.

Corresponding to the discussions in the previous subsections, we address three problems of estimating the variance components σ_1^2 , σ_2^2 and (σ_1^2, σ_a^2) on the basis of $(S_1, T_1, \dots, T_\ell)$ where $\sigma_2^2 = \sigma_1^2 + \lambda \sigma_a^2$ for

$$(2.32) \quad \lambda = \sum_{i=1}^{\ell} \lambda_i m_i / \sum_{i=1}^{\ell} m_i = \sum_{i=1}^{\ell} \lambda_i m_i / n_2.$$

Let $S_2 = \sum_{i=1}^{\ell} T_i$. Then we can verify that all the results obtained in the previous subsections hold in the model (2.27) by replacing the n_1 , n_2 , S_1 , S_2 and r in Subsection 2.1 with n_1 , n_2 , S_1 , S_2 and λ in this subsection, respectively. Especially, the results corresponding to Propositions 2.1 and 2.2 are provided as follows:

PROPOSITION 2.5. *Under the same conditions as in Proposition 2.1, the estimator $S_1 \phi(S_2/S_1)$ of the form (2.14) dominates $a_1 S_1$ relative to the loss $L(\bar{\sigma}_1^2, \sigma_1^2)$ for $L(a, b)$ given by (2.11).*

PROPOSITION 2.6. *Under the same conditions as in Proposition 2.2, the estimator $S_2 \phi(S_1/S_2)$ of the form (2.17) dominates $a_2 S_2$ relative to the loss $L(\bar{\sigma}_2^2, \sigma_2^2)$.*

The proofs are given in the next subsection. For the simultaneous estimation of (σ_1^2, σ_a^2) , combining Propositions 2.5 and 2.6 and the same arguments as used around (2.20) provides a dominance result relative to the loss $n_1 L(\bar{\sigma}_1^2, \sigma_1^2) + n_2 L(\bar{\sigma}_1^2 + \lambda \bar{\sigma}_a^2, \sigma_1^2 + \lambda \sigma_a^2)$. Unbiased estimators and the corresponding improved estimators of σ_1^2 , σ_2^2 and σ_a^2 have the same forms as given in Subsection 2.2 with replacing r with λ .

Following the results in Subsection 2.3, we can get the robustness of the above dominance results within the class of densities C_0 . The class C_1 of multivariate t -distributions guarantees the robustness of the dominance results in estimation of σ_1^2 .

2.5. Proofs

We here prove Propositions 2.5 and 2.6 in the general model (2.27) since Propositions 2.1 and 2.2 are included by Propositions 2.5 and 2.6.

The key tool for these proofs is the *Integral-Expression-of-Risk-Difference* (IERD) method given by Takeuchi (1991) and Kubokawa (1994, 99) in estimation of a scale parameter. The IERD method is, through the fundamental theorem of calculus, to give an integral-expression for a difference of risks of two estimators. For other instances in which the IERD method was applied, see Kubokawa (1998, 99), Kubokawa and Srivastava (1996) and Kubokawa *et al.* (1993).

PROOF of PROPOSITIONS 2.1 and 2.5. Since $\lim_{w \rightarrow \infty} \phi(w) = a_1$, from the IERD method of Kubokawa (1994a, b), we have

$$\begin{aligned}
 (2.33) \quad & R_1(\omega; a_1 S_1) - R_1\left(\omega; S_1 \phi\left(\frac{S_2}{S_1}\right)\right) \\
 &= E\left[\left\{\frac{S_1}{\sigma_1^2} \phi\left(\frac{S_2}{S_1} t\right) - \log \frac{S_1}{\sigma_1^2} \phi\left(\frac{S_2}{S_1} t\right) - 1\right\} \Big|_{t=1}^{\infty}\right] \\
 &= E\left[\int_1^{\infty} \frac{d}{dt} \left\{\frac{S_1}{\sigma_1^2} \phi\left(\frac{S_2}{S_1} t\right) - \log \frac{S_1}{\sigma_1^2} \phi\left(\frac{S_2}{S_1} t\right) - 1\right\} dt\right].
 \end{aligned}$$

Let $v = S_1/\sigma_1^2$, $u_i = T_i/(\sigma_1^2 + \lambda_i \sigma_a^2)$ and $\theta_i = 1 + \lambda_i \sigma_a^2/\sigma_1^2$. Carrying out the differentiation in (2.33) gives

$$\begin{aligned}
 & E\left[\int_1^{\infty} \left\{\frac{S_1}{\sigma_1^2} - \frac{1}{\phi(S_2 t/S_1)}\right\} \frac{S_2}{S_1} \phi'\left(\frac{S_2}{S_1} t\right) dt\right] \\
 &= \int \cdots \int_1^{\infty} \left\{v - \frac{1}{\phi(\sum \theta_i u_i v/t)}\right\} (\sum \theta_i u_i/v) \phi'(\sum \theta_i u_i v/t) dt \\
 &\quad \times c v^{n_1/2-1} (\prod_i u_i^{m_i/2-1}) g\left(v + \sum_i u_i\right) dv \prod_i du_i,
 \end{aligned}$$

for $c = c_{n_1} \prod_{i=1}^{\ell} c_{m_i}$. Making the transformations $(t/v)u_i = w_i$ and $1/t = z$ in order, we observe that the r.h.s. of (2.33) is equal to

$$\begin{aligned}
 (2.34) \quad & \int \cdots \int_1^{\infty} \left\{v - \frac{1}{\phi(\sum \theta_i w_i)}\right\} (\sum \theta_i w_i/t) \phi'(\sum \theta_i w_i/t) \\
 &\quad \times c (\prod_i w_i^{m_i/2-1}) v^{(n_1+n_2)/2-1} t^{-n_2/2} g((1 + \sum_i w_i/t)v) dt dv \prod_i dw_i \\
 &= \int \cdots \int \left\{v - \frac{1}{\phi(\sum \theta_i w_i)}\right\} (\sum \theta_i w_i) \phi'(\sum \theta_i w_i) \\
 &\quad \times c (\prod_i w_i^{m_i/2-1}) v^{(n_1+n_2)/2-1} \int_0^1 z^{n_2/2-1} g((1 + \sum_i w_i z)v) dz dv \prod_i dw_i.
 \end{aligned}$$

Since $\phi'(w) \geq 0$, it is concluded that the r.h.s. of (2.34) is non-negative if

$$\begin{aligned}
 (2.35) \quad \phi(\sum \theta_i w_i) &\geq \frac{\int_0^{\infty} v^{(n_1+n_2)/2-1} \int_0^1 z^{n_2/2-1} g((1 + \sum_i w_i z)v) dz dv}{\int_0^{\infty} v^{(n_1+n_2)/2} \int_0^1 z^{n_2/2-1} g((1 + \sum_i w_i z)v) dz dv} \\
 &= \frac{\int_0^{\sum w_i} x^{n_2/2-1} (1+x)^{-(n_1+n_2)/2} dx}{\int_0^{\sum w_i} x^{n_2/2-1} (1+x)^{-(n_1+n_2)/2-1} dx} \frac{\int_0^{\infty} y^{(n_1+n_2)/2-1} g(y) dy}{\int_0^{\infty} y^{(n_1+n_2)/2} g(y) dy} \\
 &= \phi_0(\sum_i w_i) A_{n_1+n_2}(g).
 \end{aligned}$$

Since $\theta_i \geq 1$ and $\phi'(w) \geq 0$, it follows that $\phi(\sum_i \theta_i w_i) \geq \phi(\sum_i w_i)$, which, from (2.35), gives the sufficient condition that $\phi(\sum w_i)$ is greater than or equal to the r.h.s. of (2.35). This is guaranteed by the condition (b) of Propositions 2.1 and 2.5, which are established. $\square \square$

PROOF of PROPOSITIONS 2.2 and 2.6. Since $\lim_{w \rightarrow \infty} \phi(w) = a_2$, observe that

$$\begin{aligned}
(2.36) \quad R_2(\omega; a_2 S_2) - R_2\left(\omega; S_2 \phi\left(\frac{S_1}{S_2}\right)\right) \\
= -E\left[\int_0^1 \frac{d}{dt} \left\{ \frac{S_2}{\sigma_1^2 + \lambda \sigma_a^2} \phi\left(\frac{S_1}{S_2} t\right) - \log \frac{S_2}{\sigma_1^2 + \lambda \sigma_a^2} \phi\left(\frac{S_1}{S_2} t\right) - 1 \right\} dt\right] \\
= \int \cdots \int_0^1 \left\{ \frac{1}{\phi(vt/\Sigma \theta_i u_i)} - \frac{\Sigma \theta_i u_i}{1 + \lambda \tau} \right\} \frac{v}{\Sigma \theta_i u_i} \phi'\left(\frac{vt}{\Sigma \theta_i u_i}\right) dt \\
\times c v^{n_1/2-1} (\prod_i u_i^{m_i/2-1}) g(v + \Sigma_i u_i) dv \prod_i du_i,
\end{aligned}$$

for $\tau = \sigma_a^2/\sigma_1^2$. Making the transformations $(t/\Sigma \theta_i u_i)v = w$ and $w(1/t) = z$ in order, we can rewrite (2.36) as

$$\begin{aligned}
(2.37) \quad \int \cdots \int_0^1 \left\{ \frac{1}{\phi(w)} - \frac{\Sigma \theta_i u_i}{1 + \lambda \tau} \right\} \phi'(w) w \Sigma \theta_i u_i / t^2 \\
\times c (\Sigma_i \theta_i u_i w t^{-1})^{n_1/2-1} (\prod_i u_i^{m_i/2-1}) g(\Sigma_i \theta_i u_i w t^{-1} + \Sigma_i u_i) dt \prod_i du_i dw \\
= \int \cdots \int_w \left\{ \frac{1}{\phi(w)} - \frac{\Sigma \theta_i u_i}{1 + \lambda \tau} \right\} \phi'(w) \Sigma \theta_i u_i \\
\times c (\Sigma_i \theta_i u_i z)^{n_1/2-1} (\prod_i u_i^{m_i/2-1}) g(\Sigma_i \theta_i u_i z + \Sigma_i u_i) dz \prod_i du_i dw,
\end{aligned}$$

so that since $\phi'(w) \geq 0$, the l.h.s. of (2.36) is nonnegative if

$$(2.38) \quad \phi(w) \leq \frac{\int \cdots \int_w (\Sigma \theta_i u_i) (\Sigma \theta_i u_i z)^{n_1/2-1} (\prod_i u_i^{m_i/2-1}) g(\Sigma \theta_i u_i z + \Sigma u_i) dz \prod_i du_i}{\int \cdots \int_w (\Sigma \theta_i u_i)^2 / (1 + \lambda \tau) (\Sigma \theta_i u_i z)^{n_1/2-1} (\prod_i u_i^{m_i/2-1}) g(\Sigma \theta_i u_i z + \Sigma u_i) dz \prod_i du_i}.$$

Let $s = \sum_{i=1}^{\ell} u_i$ and $t_i = u_i/s$ for $i = 1, \dots, \ell$. The numerator of the r.h.s. of (2.38) is written as

$$\begin{aligned}
& \int \cdots \int_w (\Sigma \theta_i u_i)^{n_1/2} z^{n_1/2-1} (\prod_i u_i^{m_i/2-1}) g(\Sigma \theta_i u_i z + \Sigma u_i) dz \prod_i du_i \\
&= \int \cdots \int_w (\Sigma \theta_i t_i)^{n_1/2} z^{n_1/2-1} s^{(n_1+n_2)/2-1} g((\Sigma \theta_i t_i z + 1)s) dz ds \frac{\prod_i t_i^{m_i/2-1}}{t_1 \cdots t_{\ell-1}} \prod_{i=1}^{\ell-1} dt_i \\
&= \int \cdots \int_{\Sigma \theta_i t_i w} x^{n_1/2-1} s^{(n_1+n_2)/2-1} g((1+x)s) dx ds \frac{\prod_i t_i^{m_i/2-1}}{t_1 \cdots t_{\ell-1}} \prod_{i=1}^{\ell-1} dt_i \\
&= \int \cdots \int_{\Sigma \theta_i t_i w} x^{n_1/2-1} (1+x)^{-(n_1+n_2)/2} dx \frac{\prod_i t_i^{m_i/2-1}}{t_1 \cdots t_{\ell-1}} \prod_{i=1}^{\ell-1} dt_i \int y^{(n_1+n_2)/2-1} g(y) dy.
\end{aligned}$$

Similarly, we have that

$$\begin{aligned}
& \int \cdots \int_w (\Sigma \theta_i u_i)^{n_1/2+1} z^{n_1/2-1} (\prod_i u_i^{m_i/2-1}) g(\Sigma \theta_i u_i z + \Sigma u_i) dz \prod_i du_i \\
&= \int \cdots \int_{\Sigma \theta_i t_i w} (\Sigma \theta_i t_i) x^{n_1/2-1} (1+x)^{-(n_1+n_2)/2-1} dx \frac{\prod_i t_i^{m_i/2-1}}{t_1 \cdots t_{\ell-1}} \prod_{i=1}^{\ell-1} dt_i \\
&\quad \times \int y^{(n_1+n_2)/2} g(y) dy.
\end{aligned}$$

Let $Q = \Sigma_i \theta_i t_i$, and the density of Q is written by

$$f_Q(q) = (\text{const.}) \int \cdots \int_{\sum_i \theta_i t_i = q} \frac{\prod t_i^{m_i/2-1}}{t_1 \cdots t_{\ell-1}} \prod_{i=1}^{\ell-1} dt_i.$$

When we denote the expectation with respect to Q by $E^Q[\cdot]$, the r.h.s. of (2.38) is expressed by

$$(2.39) \quad \frac{E^Q \left[\int_{Qw}^{\infty} x^{n_1/2-1} (1+x)^{-(n_1+n_2)/2} dx \right]}{E^Q \left[Q(1+\lambda\tau)^{-1} \int_{Qw}^{\infty} x^{n_1/2-1} (1+x)^{-(n_1+n_2)/2-1} dx \right]} A_{n_1+n_2}(g).$$

Since Q and $\int_{Qw}^{\infty} x^{n_1/2-1} (1+x)^{-(n_1+n_2)/2-1} dx$ are monotone in the opposite directions, by using Theorem 1.10.5 of Srivastava and Khatri (1979), we can show the following inequality for the denominator of the r.h.s. of (2.39):

$$(2.40) \quad \begin{aligned} E^Q \left[\frac{Q}{1+\lambda\tau} \int_{Qw}^{\infty} x^{n_1/2-1} (1+x)^{-(n_1+n_2)/2-1} dx \right] \\ \leq E^Q \left[\frac{Q}{1+\lambda\tau} \right] E^Q \left[\int_{Qw}^{\infty} x^{n_1/2-1} (1+x)^{-(n_1+n_2)/2-1} dx \right]. \end{aligned}$$

Here observe that

$$(2.41) \quad \begin{aligned} E^Q \left[\frac{Q}{1+\lambda\tau} \right] &= \frac{1}{1+\lambda\tau} + \frac{1}{1+\lambda\tau} \sum_{i=1}^{\ell} \lambda_i \tau E[z_i] \\ &= \frac{1}{1+\lambda\tau} + \frac{1}{1+\lambda\tau} \frac{\sum \lambda_i \tau m_i}{n_2} = 1, \end{aligned}$$

since $\lambda = \sum \lambda_i m_i / n_2$. Combining (2.38), (2.39), (2.40) and (2.41) gives a sufficient condition as

$$(2.42) \quad \phi(w) \leq \frac{E^Q \left[\int_{Qw}^{\infty} x^{n_1/2-1} (1+x)^{-(n_1+n_2)/2} dx \right]}{E^Q \left[\int_{Qw}^{\infty} x^{n_1/2-1} (1+x)^{-(n_1+n_2)/2-1} dx \right]} A_{n_1+n_2}(g).$$

For the r.h.s. of (2.42), we can easily check that

$$\begin{aligned} \frac{E^Q \left[\int_{Qw}^{\infty} x^{n_1/2-1} (1+x)^{-(n_1+n_2)/2} dx \right]}{E^Q \left[\int_{Qw}^{\infty} x^{n_1/2-1} (1+x)^{-(n_1+n_2)/2-1} dx \right]} &\geq \inf_{Q \geq 1} \left\{ \frac{\int_{Qw}^{\infty} x^{n_1/2-1} (1+x)^{-(n_1+n_2)/2} dx}{\int_{Qw}^{\infty} x^{n_1/2-1} (1+x)^{-(n_1+n_2)/2-1} dx} \right\} \\ &= \inf_{Q \geq 1} \{ \phi_0(Qw) \}, \end{aligned}$$

which is equal to $\phi_0(w)$ since $\phi_0(\cdot)$ is nondecreasing. Hence we get the sufficient condition that $\phi(w) \leq \phi_0(w) A_{n_1+n_2}(g)$, which is just the condition (b), and the proofs of Propositions 2.2 and 2.6 are complete. $\square \square$

3. Estimation of covariance components in a multivariate random effect model

In this section, we provide a multivariate extension of some results of

Section 2. An elliptically contoured distribution model which corresponds to a one-way multivariate random effects model is given and its canonical form is derived in Subsection 3.1. Dominance results for estimation of ‘within’ component of variance Σ_1 are developed in Subsections 3.2 and 3.3, and their robustness is discussed in Subsection 3.4. Estimation of ‘between’ component of variance Σ_A and function $\Sigma_2 = \Sigma_1 + r\Sigma_A$ is studied in Subsection 3.5.

3.1. A multivariate random effect model and its canonical form

Let y_{ij} 's be p -variate random variables for $i=1, \dots, k$ and $j=1, \dots, r$, and let $\mathbf{y} = (\mathbf{y}_1^t, \dots, \mathbf{y}_k^t)$ for $\mathbf{y}_i = (\mathbf{y}_{i1}^t, \dots, \mathbf{y}_{ir}^t)^t$. Suppose that $\mathbf{y}$ has the following model with a covariance structure of the multivariate intraclass correlation:

$$(3.1) \quad \mathbf{y} = \mathbf{J}_N \otimes \boldsymbol{\mu} + \mathbf{u},$$

where $N = kr$, $\boldsymbol{\mu} \in \mathbf{R}^p$ is an unknown vector and $\mathbf{u}$ is a pN -variate error vector. Assume that the error has an elliptical density

$$|\boldsymbol{\Omega}|^{-1/2} f(\mathbf{u}^t \boldsymbol{\Omega}^{-1} \mathbf{u}),$$

where $\boldsymbol{\Omega}$ is a $(pN) \times (pN)$ matrix with the multivariate intraclass correlation structure

$$\boldsymbol{\Omega} = \mathbf{I}_N \otimes \Sigma_1 + \mathbf{I}_k \otimes \mathbf{J}_r \otimes \Sigma_A,$$

for $p \times p$ positive definite matrices Σ_1 and Σ_A . This structure corresponds to the one-way multivariate mixed linear model under the normality:

$$\mathbf{u} = (\mathbf{I}_k \otimes \mathbf{j}_r \otimes \mathbf{I}_p) \boldsymbol{\alpha} + \boldsymbol{\varepsilon},$$

where $\boldsymbol{\alpha}$ and $\boldsymbol{\varepsilon}$ are independent random variables with $\boldsymbol{\alpha} \sim \mathcal{N}_{pk}(\mathbf{0}, \mathbf{I}_k \otimes \Sigma_A)$ and $\boldsymbol{\varepsilon} \sim \mathcal{N}_{pN}(\mathbf{0}, \mathbf{I}_N \otimes \Sigma_1)$. Namely, $y_{ij} = \mu_i + \alpha_i + \varepsilon_{ij}$ for $i=1, \dots, k$ and $j=1, \dots, r$, where $\alpha_i \sim \mathcal{N}_p(\mathbf{0}, \Sigma_A)$ and $\varepsilon_{ij} \sim \mathcal{N}_p(\mathbf{0}, \Sigma_1)$.

The $N \times N$ matrix $\mathbf{H}$ defined in Section 2.1 is employed to get a canonical form. Letting $\mathbf{Y} = (\mathbf{y}_{11}, \dots, \mathbf{y}_{ir}; \dots; \mathbf{y}_{k1}, \dots, \mathbf{y}_{kr})$, we see that

$$\begin{aligned} (\mathbf{H} \otimes \mathbf{I}_p) \mathbf{y} &= \text{vec}(\mathbf{YH}^t) \\ &= \text{vec}(\sqrt{N} \bar{\mathbf{y}}, \mathbf{YH}_2^t) \\ &= \begin{pmatrix} \sqrt{N} \bar{\mathbf{y}} \\ \text{vec}(\mathbf{YH}_2^t) \end{pmatrix}. \end{aligned}$$

Also we observe that

$$(\mathbf{H} \otimes \mathbf{I}_p)(\mathbf{j}_N \otimes \boldsymbol{\mu}) = (\sqrt{N}, 0, \dots, 0)^t \otimes \boldsymbol{\mu},$$

and that

$$\begin{aligned} &(\mathbf{H} \otimes \mathbf{I}_p) \boldsymbol{\Omega} (\mathbf{H}^t \otimes \mathbf{I}_p) \\ &= \mathbf{I}_N \otimes \Sigma_1 + \mathbf{H}(\mathbf{I}_k \otimes \mathbf{J}_r) \mathbf{H}^t \otimes \Sigma_A \\ &= \begin{pmatrix} \Sigma_1 + r\Sigma_A & \mathbf{0} \\ \mathbf{0} & \mathbf{I}_{N-1} \otimes \Sigma_1 + \{\mathbf{H}_2(\mathbf{I}_k \otimes \mathbf{J}_r) \mathbf{H}_2^t\} \otimes \Sigma_A \end{pmatrix} \\ &= \begin{pmatrix} \Sigma_1 + r\Sigma_A & \mathbf{0} \\ \mathbf{0} & \mathbf{E}_1 \otimes \Sigma_1 + \mathbf{E}_2 \otimes (\Sigma + r\Sigma_A) \end{pmatrix}, \end{aligned}$$

where E_1 and E_2 are idempotent matrices defined in Section 2.1 such that $E_1 + E_2 = I_{N-1}$. We thus write the quadratic form $u^t \Omega^{-1} u$ as

$$\begin{aligned} & (y - j_N \otimes \mu)^t \Omega^{-1} (y - j_N \otimes \mu) \\ &= \begin{pmatrix} \sqrt{N} \bar{y} - \sqrt{N} \mu \\ \text{vec}(YH_2^t) \end{pmatrix}^t \begin{pmatrix} \Sigma_1 + r\Sigma_A & 0 \\ 0 & E_1 \otimes \Sigma_1 + E_2 \otimes (\Sigma + r\Sigma_A) \end{pmatrix}^{-1} \\ & \quad \times \begin{pmatrix} \sqrt{N} \bar{y} - \sqrt{N} \mu \\ \text{vec}(YH_2^t) \end{pmatrix} \\ &= N(\bar{y} - \mu)^t (\Sigma_1 + r\Sigma_A)^{-1} (\bar{y} - \mu) \\ & \quad + \{\text{vec}(YH_2^t)\}^t \{E_1 \otimes \Sigma_1^{-1} + E_2 \otimes (\Sigma_1 + r\Sigma_A)^{-1}\} \text{vec}(YH_2^t). \end{aligned}$$

By integrating out with respect to $\sqrt{N} \bar{y}$, the density of YH_2^t can be written by

$$|\Sigma_1|^{-n_1/2} |\Sigma_2|^{-n_2/2} g(\text{tr } \Sigma_1^{-1} YH_2^t E_1 H_2 Y^t + \text{tr } \Sigma_2^{-1} YH_2^t E_2 H_2 Y^t),$$

where $n_1 = N - k$, $n_2 = k - 1$, $\Sigma_2 = \Sigma_1 + r\Sigma_A$, and

$$g(a) = \int |\Sigma_2|^{-1/2} f(N(\bar{y} - \mu)^t \Sigma_2^{-1} (\bar{y} - \mu) + a) d(\sqrt{N} \bar{y}).$$

Let $S_1 = YH_2^t E_1 H_2 Y^t$. Since E_1 is an idempotent matrix with rank n_1 , we can take $p \times n_1$ matrix x such that $S_1 = xx^t$. The matrix x can be written as $x = TK$ where T is a $p \times p$ low-triangular matrix with positive diagonal elements and K is a $p \times n_1$ matrix with $KK^t = I_p$. The usual technique used in the theory of multivariate analysis gives that

$$dx^t = 2^{-p} |S_1|^{(n_1-p-1)/2} (dS_1) K d(K^t)$$

and

$$\int_{V_{p,n_1}} K d(K^t) = 2^p \pi^{pn_1/2} / \Gamma_p(n_1/2),$$

where $\Gamma_p(a) = \pi^{p(p-1)/4} \prod_{i=1}^p \Gamma(a - 2^{-1}(i-1))$ for $a > (p-1)/2$, and V_{p,n_1} designates the Stiefel manifold of $n_1 \times p$ matrix with orthonormal columns (see Srivastava and Khatri (1979)). Hence the joint density of $(S_1, YH_2^t E_2)$ is expressed by

$$c_{p,n_1} |\Sigma_1|^{-n_1/2} |\Sigma_2|^{-n_2/2} |S_1|^{(n_1-p-1)/2} g(\text{tr } \Sigma_1^{-1} S_1 + \text{tr } \Sigma_2^{-1} YH_2^t E_2 H_2 Y^t),$$

where

$$(3.2) \quad c_{p,n_1} = \pi^{pn_1/2} / \Gamma_p(n_1/2).$$

Also let $S_2 = YH_2^t E_2 H_2 Y^t$. Then the same arguments can be used to provide the joint density of (S_1, S_2) as

$$(3.3) \quad c_{p,n_1} c_{p,n_2} |\Sigma_1|^{-n_1/2} |\Sigma_2|^{-n_2/2} |S_1|^{(n_1-p-1)/2} |S_2|^{(n_2-p-1)/2} g(\text{tr } \Sigma_1^{-1} S_1 + \text{tr } \Sigma_2^{-1} S_2).$$

Similar to (2.9) and (2.10), S_1 and S_2 are represented by

$$\begin{aligned}
S_1 &= Y \left(I_{kr} - \frac{1}{r} I_k \otimes J_r \right) Y^t \\
&= \sum_{i=1}^k \sum_{j=1}^r (\mathbf{y}_{ij} - \bar{\mathbf{y}}_{i.})(\mathbf{y}_{ij} - \bar{\mathbf{y}}_{i.})^t, \\
S_2 &= Y \left(\frac{1}{r} I_k \otimes J_r - \frac{1}{rk} J_{rk} \right) Y^t \\
&= r \sum_{i=1}^k (\bar{\mathbf{y}}_{i.} - \bar{\mathbf{y}}_{..})(\bar{\mathbf{y}}_{i.} - \bar{\mathbf{y}}_{..})^t,
\end{aligned}$$

where $\bar{\mathbf{y}}_{i.} = r^{-1} \sum_{j=1}^r \mathbf{y}_{ij}$ and $\bar{\mathbf{y}}_{..} = (rk)^{-1} \sum_{i=1}^k \sum_{j=1}^r \mathbf{y}_{ij}$. It is noted that $\Sigma_1 \leq \Sigma_2$ where $\Sigma_1 \leq \Sigma_2$ denotes that $\Sigma_2 - \Sigma_1$ is nonnegative definite. Based on S_1 , S_2 and their joint density (3.3), we shall address the problems of estimating Σ_1 , Σ_2 and Σ_A in the next section.

3.2. Improvement on an unbiased estimator of 'within' component of variance

We now consider the problem of estimating Σ_1 relative to the Stein (or entropy) loss function

$$(3.4) \quad L(\hat{\Sigma}_1, \Sigma_1) = \text{tr } \hat{\Sigma}_1 \Sigma_1^{-1} - \log |\hat{\Sigma}_1 \Sigma_1^{-1}| - p,$$

where every estimator $\hat{\Sigma}_1$ is evaluated by the risk function $R_1(\omega; \hat{\Sigma}_1) = E_\omega[L(\hat{\Sigma}_1, \Sigma_1)]$ for $\omega \in \Omega = \{(\Sigma_1, \Sigma_2) | \Sigma_1 \leq \Sigma_2\}$.

We begin with deriving an unbiased estimator of Σ_1 based on S_1 only.

PROPOSITION 3.1. For $A_k(g)$ defined in (2.13), let

$$(3.5) \quad A_g^* = p(n_1 + n_2) A_{p(n_1+n_2)}(g).$$

Then an unbiased estimator of Σ_1 is given by

$$(3.6) \quad \hat{\Sigma}_1^{UB}(g) = \frac{1}{n_1} S_1 \cdot A_g^*,$$

which has the risk function

$$(3.7) \quad R_1(\omega; \hat{\Sigma}_1^{UB}(g)) = E[p \log n_1 - \log |S_1 A_g^*|].$$

PROOF. Let $T_1 = (t_{ij})$ be a lower triangular matrix with positive diagonal elements such that $\Sigma_1^{-1/2} S_1 \Sigma_1^{-1/2} = T_1 T_1^t$. Since $dS_1 = 2^p \prod_{i=1}^p t_{ii}^{p+1-i} dT_1$, for $c = C_{p,n_1} C_{p,n_2}$, we have

$$\begin{aligned}
(3.8) \quad & \Sigma_1^{-1/2} E[S_1] \Sigma_1^{-1/2} \\
&= \iint c S_1 |S_1|^{(n_1-p-1)/2} |S_2|^{(n_2-p-1)/2} g(\text{tr } S_1 + \text{tr } S_2) dS_1 dS_2 \\
&= 2c \iint T_1 T_1^t t_{11}^{n_1-1} t_{22}^{n_1-2} \dots t_{pp}^{n_1-p} |S_2|^{(n_2-p-1)/2} \\
&\quad \cdot g\left(\sum_{i=1}^p (t_{i1}^2 + \dots + t_{ii}^2) + \text{tr } S_2\right) dT_1 dS_2
\end{aligned}$$

$$= \frac{\int \cdot \int \text{diag}(x_1, \dots, x_p) \prod_{i=1}^p x_i^{n_1/2-1} |S_2|^{(n_2-p-1)/2} g(\sum_{i=1}^p x_i + \text{tr } S_2) \prod_i dx_i dS_2}{\int \cdot \int \prod_{i=1}^p x_i^{n_1/2-1} |S_2|^{(n_2-p-1)/2} g(\sum_{i=1}^p x_i + \text{tr } S_2) \prod_i dx_i dS_2},$$

where the transformation $x_i = t_{i1}^2 + \dots + t_{ii}^2$ is made. The same arguments are applied to the random matrix S_2 , and the r.h.s. of (3.8) is rewritten by

$$\frac{\int \cdot \int \text{diag}(x_1, \dots, x_p) \prod_{i=1}^p x_i^{n_1/2-1} y^{pn_2/2-1} g(\sum_{i=1}^p x_i + y) \prod_i dx_i dy}{\int \cdot \int \prod_{i=1}^p x_i^{n_1/2-1} y^{pn_2/2-1} g(\sum_{i=1}^p x_i + y) \prod_i dx_i dy}.$$

For $j=1, \dots, p$, making the transformation $z = \sum_{i \neq j} x_i + y$ again gives

$$(3.9) \quad \frac{\int \cdot \int x_j \prod_{i=1}^p x_i^{n_1/2-1} y^{pn_2/2-1} g(\sum_{i=1}^p x_i + y) \prod_i dx_i dy}{\int \cdot \int \prod_{i=1}^p x_i^{n_1/2-1} y^{pn_2/2-1} g(\sum_{i=1}^p x_i + y) \prod_i dx_i dy} \\ = \frac{\int \cdot \int x_j^{n_1/2} z^{\{(p-1)n_1 + pn_2\}/2-1} g(x_j + z) \prod_i dx_j dz}{\int \cdot \int x_j^{n_1/2-1} z^{\{(p-1)n_1 + pn_2\}/2-1} g(x_j + z) \prod_i dx_j dz}.$$

Making the transformations $v = x_j + z$ and $w = z/(x_j + z)$ with $J((x_j, z) \rightarrow (v, w)) = v$, the r.h.s. of (3.9) is expressed by

$$\frac{\int \cdot \int w^{\{(p-1)n_1 + pn_2\}/2-1} (1-w)^{n_1/2} v^{p(n_1+n_2)/2} g(v) dw dv}{\int \cdot \int w^{\{(p-1)n_1 + pn_2\}/2-1} (1-w)^{n_1/2-1} v^{p(n_1+n_2)/2-1} g(v) dw dv} \\ = n_1 \{p(n_1 + n_2) A_{p(n_1+n_2)}(g)\}^{-1},$$

which yields the unbiased estimator (3.6). The risk function (3.7) can be easily derived. $\square\square$

We now provide a general truncation rule for improving upon estimators based on S_1 like $\hat{\Sigma}_1^{UB}(g)$ by employing the information on the order restriction that $\Sigma_1 \leq \Sigma_2$. The estimators which we treat are of the general form

$$(3.10) \quad \hat{\Sigma}_1(\Psi, g) = S_1^{1/2} P \Psi(\Lambda) P^t S_2^{1/2} A_g^*$$

for

$$\Psi(\Lambda) = \text{diag}(\phi_1(\Lambda), \dots, \phi_p(\Lambda)),$$

where $S_2^{1/2}$ is a symmetric matrix such that $S_2 = (S_2^{1/2})^2$ and P is an orthogonal $p \times p$ matrix such that

$$\mathbf{P}^t \mathbf{S}_2^{-1/2} \mathbf{S}_1 \mathbf{S}_2^{-1/2} \mathbf{P} = \mathbf{\Lambda} = \text{diag}(\lambda_1, \dots, \lambda_p)$$

with $\lambda_1 \geq \lambda_2 \geq \dots \geq \lambda_p$, and $\phi_i(\mathbf{\Lambda})$'s are non-negative functions of $\mathbf{\Lambda}$. For given estimator $\hat{\Sigma}_1(\Psi, g)$, we define a truncation rule $[\Psi(\mathbf{\Lambda})]^{TR}$ by

$$(3.11) \quad \begin{aligned} [\Psi(\mathbf{\Lambda})]^{TR} &= \text{diag}(\phi_1^{TR}(\mathbf{\Lambda}), \dots, \phi_p^{TR}(\mathbf{\Lambda})), \\ \phi_i^{TR}(\mathbf{\Lambda}) &= \min\left\{\phi_i(\mathbf{\Lambda}), \frac{\lambda_i + 1}{n_1 + n_2}\right\}, \quad i=1, \dots, p, \end{aligned}$$

which gives the corresponding truncated estimator of the form

$$(3.12) \quad \hat{\Sigma}_1([\Psi]^{TR}, g) = \mathbf{S}_2^{1/2} \mathbf{P} \text{diag}(\phi_1^{TR}(\mathbf{\Lambda}), \dots, \phi_p^{TR}(\mathbf{\Lambda})) \mathbf{P}^t \mathbf{S}_2^{1/2} \mathbf{A}_g^*.$$

Then we get the following general dominance result.

THEOREM 3.1. *The estimator $\hat{\Sigma}_1([\Psi]^{TR}, g)$ dominates $\hat{\Sigma}_1(\Psi, g)$ relative to the Stein loss (3.4) if $P[[\Psi(\mathbf{\Lambda})]^{TR} \neq \Psi(\mathbf{\Lambda})] > 0$ at some $\omega \in \Omega$.*

PROOF. Without any loss of generality, let $\Sigma_1 = \mathbf{I}$ and $\Sigma_2 = \Theta = \text{diag}(\theta_1, \dots, \theta_p)$ with $\theta_1 > 1, \dots, \theta_p \geq 1$. The joint density of $\mathbf{S}_1$ and $\mathbf{S}_2$ is

$$\text{const.} |\mathbf{S}_1|^{(n_1-p-1)/2} |\mathbf{S}_2|^{(n_2-p-1)/2} |\Theta|^{-n_2/2} g(\text{tr}(\mathbf{S}_1 + \Theta^{-1} \mathbf{S}_2)).$$

Making the transformation $\mathbf{F} = \mathbf{S}_2^{-1/2} \mathbf{S}_1 \mathbf{S}_2^{-1/2}$ with $J(\mathbf{S}_1 \rightarrow \mathbf{F}) = |\mathbf{S}_2|^{(p+1)/2}$ gives the joint density of $\mathbf{F}$ and $\mathbf{S}_2$:

$$(3.13) \quad f_{\mathbf{F}, \mathbf{S}_2}(\mathbf{F}, \mathbf{S}_2) = \text{const.} |\mathbf{F}|^{(n_1-p-1)/2} |\mathbf{S}_2|^{(n_1+n_2-p-1)/2} |\Theta|^{-n_2/2} g(\text{tr}(\mathbf{F} + \Theta^{-1} \mathbf{S}_2)).$$

Making the transformation $\mathbf{F} = \mathbf{P} \mathbf{\Lambda} \mathbf{P}^t$, we see that the joint density of $(\mathbf{\Lambda}, \mathbf{P}, \mathbf{S}_2)$ is written by

$$f_{\mathbf{\Lambda}, \mathbf{P}, \mathbf{S}_2}(\mathbf{\Lambda}, \mathbf{P}, \mathbf{S}_2) = \text{const.} f_p(\mathbf{P}) h(\mathbf{\Lambda}) |\mathbf{S}_2|^{(n_1+n_2-p-1)/2} |\Theta|^{-n_2/2} g(\text{tr}(\mathbf{P} \mathbf{\Lambda} \mathbf{P}^t + \Theta^{-1} \mathbf{S}_2)),$$

where $f_p(\mathbf{P}) = J(\mathbf{P}^t d\mathbf{P} \rightarrow d\mathbf{P})$ and $h(\mathbf{\Lambda})$ is a function of $\mathbf{\Lambda}$ (see Srivastava and Khatri (1979, p.31-32)). Hence the conditional expectation of $\mathbf{S}_2$ given $(\mathbf{\Lambda}, \mathbf{P})$ is written by

$$(3.14) \quad \begin{aligned} & (\mathbf{P} \mathbf{\Lambda} \mathbf{P}^t + \Theta^{-1})^{1/2} E[\mathbf{S}_2 | \mathbf{\Lambda}, \mathbf{P}] (\mathbf{P} \mathbf{\Lambda} \mathbf{P}^t + \Theta^{-1})^{1/2} \\ &= \frac{\int \mathbf{S}_2 |\mathbf{S}_2|^{(n_1+n_2-p-1)/2} g(\text{tr} \mathbf{S}_2) d\mathbf{S}_2}{\int |\mathbf{S}_2|^{(n_1+n_2-p-1)/2} g(\text{tr} \mathbf{S}_2) d\mathbf{S}_2}. \end{aligned}$$

From the same arguments as in the proof of Proposition 3.1, we see that the r. h.s. of (3.14) is equal to

$$\mathbf{I}_p \{p A_{p(n_1+n_2)}(g)\}^{-1},$$

so that

$$(3.15) \quad \begin{aligned} E[\mathbf{S}_2 | \mathbf{\Lambda}, \mathbf{P}] &= (\mathbf{P} \mathbf{\Lambda} \mathbf{P}^t + \Theta^{-1})^{-1} \{p A_{p(n_1+n_2)}(g)\}^{-1} \\ &\geq (\mathbf{P} \mathbf{\Lambda} \mathbf{P}^t + \mathbf{I}_p)^{-1} \{p A_{p(n_1+n_2)}(g)\}^{-1}. \end{aligned}$$

The difference of the risk functions of $\hat{\Sigma}_1(\Psi)$ and $\hat{\Sigma}_1([\Psi]^{TR})$ is written as

$$\begin{aligned}
(3.16) \quad & R_1(\omega, \widehat{\Sigma}_1(\Psi, g)) - R_1(\omega, \widehat{\Sigma}_1([\Psi]^{TR}, g)) \\
&= E[\text{tr}(\mathbf{P}\Psi(\Lambda)\mathbf{P}^t - \mathbf{P}[\Psi(\Lambda)]^{TR}\mathbf{P}^t)S_2A_g^* - \log|\Psi(\Lambda)\{[\Psi(\Lambda)]^{TR}\}^{-1}|] \\
&= E^{A, P}[\text{tr}(\Psi(\Lambda) - [\Psi(\Lambda)]^{TR})\mathbf{P}^t E[S_2|\Lambda, \mathbf{P}]\mathbf{P}A_g^* \\
&\quad - \log|\Psi(\Lambda)\{[\Psi(\Lambda)]^{TR}\}^{-1}|].
\end{aligned}$$

From (3.15) and the fact that $\Psi(\Lambda) \geq [\Psi(\Lambda)]^{TR}$, it follows that the r.h.s. in (3.16) is greater than or equal to

$$\begin{aligned}
(3.17) \quad & E[\text{tr}\{\Psi(\Lambda) - [\Psi(\Lambda)]^{TR}\}(n_1 + n_2)(\Lambda + \mathbf{I})^{-1} - \log|\Psi(\Lambda)\{[\Psi(\Lambda)]^{TR}\}^{-1}|] \\
&= \sum_{i=1}^p E\left[\left\{\left(\phi_i(\Lambda) - \frac{\lambda_i + 1}{n_1 + n_2}\right)\frac{n_1 + n_2}{\lambda_i + 1} - \log \phi_i(\Lambda)\frac{n_1 + n_2}{\lambda_i + 1}\right\}\right. \\
&\quad \left.\times I\left(\phi_i(\Lambda) > \frac{\lambda_i + 1}{n_1 + n_2}\right)\right] \\
&= \sum_{i=1}^p E\left[\left\{\phi_i\frac{n_1 + n_2}{\lambda_i + 1} - \log \phi_i\frac{n_1 + n_2}{\lambda_i + 1} - 1\right\}I\left(\phi_i(\Lambda) > \frac{\lambda_i + 1}{n_1 + n_2}\right)\right] \\
&\geq 0,
\end{aligned}$$

which proves Theorem 3.1. $\square\square$

Since $S_1 = S_2^{1/2}S_2^{-1/2}S_1S_2^{-1/2}S_2^{1/2} = S_2^{1/2}\mathbf{P}\mathbf{A}\mathbf{P}^tS_2^{1/2}$, the unbiased estimator $\widehat{\Sigma}_1^{UB}(g)$ given by (3.6) can be expressed in the same manner as (3.10) by

$$\widehat{\Sigma}_1^{UB}(g) = \widehat{\Sigma}_1(\Psi^{UB}, g),$$

where

$$\Psi^{UB} = \text{diag}(n_1^{-1}\lambda_1, \dots, n_1^{-1}\lambda_p).$$

The truncation rule (3.11) produces the estimator

$$(3.18) \quad \widehat{\Sigma}_1^{REML}(g) = \widehat{\Sigma}_1([\Psi^{UB}]^{TR}, g),$$

where

$$[\Psi^{UB}]^{TR} = \text{diag}\left(\min\left\{\frac{\lambda_1}{n_1}, \frac{\lambda_1 + 1}{n_1 + n_2}\right\}, \dots, \min\left\{\frac{\lambda_p}{n_1}, \frac{\lambda_p + 1}{n_1 + n_2}\right\}\right).$$

From Theorem 3.1, we get

COROLLARY 3.1. *The estimator $\widehat{\Sigma}_1^{REML}(g)$ dominates the unbiased estimator $\widehat{\Sigma}_1^{UB}(g)$ relative to the Stein loss (3.4).*

The estimator $\widehat{\Sigma}_1^{REML}(g)$ is known to be the restricted (or residual) maximum likelihood (REML) estimator of Σ_1 under the constraint $\Sigma_1 \leq \Sigma_2$.

It is interesting to note that the REML estimator $\widehat{\Sigma}_1^{REML}(g)$ can also be derived as an empirical Bayes rule. Let $\eta = \Sigma_2^{-1}$ and $\xi = \Sigma_2^{1/2}\Sigma_1^{-1}\Sigma_2^{1/2}$. Suppose that η has non-informative prior distribution $|\eta|^{-(p+1)/2}d\nu(\eta)$ for some measure $\nu(\cdot)$ and that ξ is unknown. The joint density of (η, S_1, S_2) has the form

$$\text{const.} |\eta|^{(n_1 + n_2 - p - 1)/2} |S_1|^{(n_1 - p - 1)/2} |S_2|^{(n_2 - p - 1)/2} |\xi|^{n_1/2} g(\text{tr}(\xi^{1/2}S_1\xi^{1/2} + S_2)\eta),$$

so that the posterior density given S_1 and S_2 and the marginal density of S_1 and S_2 are given by

$$\begin{aligned} \text{(posterior)} &\propto |\boldsymbol{\eta}|^{(n_1+n_2-p-1)/2} g(\text{tr}(\boldsymbol{\xi}^{1/2} S_1 \boldsymbol{\xi}^{1/2} + S_2) \boldsymbol{\eta}), \\ \text{(marginal)} &\propto |\boldsymbol{\xi}|^{n_1/2} |\boldsymbol{\xi}^{1/2} S_1 \boldsymbol{\xi}^{1/2} + S_2|^{-(n_1+n_2)/2} |S_1|^{(n_1-p-1)/2} |S_2|^{(n_2-p-1)/2}. \end{aligned}$$

From (3.15), we thus get the Bayes estimator of $\boldsymbol{\Sigma}_1$ under the Stein loss (3.4)

$$\begin{aligned} \widehat{\boldsymbol{\Sigma}}_1^B(\boldsymbol{\xi}, g) &= \boldsymbol{\xi}^{-1/2} (E[\boldsymbol{\eta} | S_1, S_2])^{-1} \boldsymbol{\xi}^{-1/2} \\ &= (n_1 + n_2)^{-1} \boldsymbol{\xi}^{-1/2} (\boldsymbol{\xi}^{1/2} S_1 \boldsymbol{\xi}^{1/2} + S_2) \boldsymbol{\xi}^{-1/2} A_g^* \\ &= (n_1 + n_2)^{-1} (S_1 + \boldsymbol{\xi}^{-1/2} S_2 \boldsymbol{\xi}^{-1/2}) A_g^*. \end{aligned}$$

Since $\boldsymbol{\xi}$ is unknown, $\boldsymbol{\xi}$ needs to be estimated from the marginal density. Putting $\boldsymbol{\beta} = S_1^{-1/2} \boldsymbol{\xi}^{-1/2} S_2 \boldsymbol{\xi}^{-1/2} S_1^{-1/2}$, the maximum likelihood estimator of $\boldsymbol{\beta}$ can be derived by maximising $|\boldsymbol{\beta}|^{n_2/2} |\mathbf{I} + \boldsymbol{\beta}|^{-(n_1+n_2)/2}$ subject to the order restriction $\boldsymbol{\beta} \leq S_1^{-1/2} S_2 S_1^{-1/2}$ since $\boldsymbol{\xi} \geq \mathbf{I}$. The resulting MLE of $\boldsymbol{\beta}$ is

$$\hat{\boldsymbol{\beta}} = \mathbf{Q} \text{diag}\left(\min\left\{\frac{n_2}{n_1}, \frac{1}{\lambda_i}\right\}, i=1, \dots, p\right) \mathbf{Q}^t,$$

where $\mathbf{Q}$ is an orthogonal $p \times p$ matrix such that

$$\mathbf{Q}^t S_1^{-1/2} S_2 S_1^{-1/2} \mathbf{Q} = \text{diag}(\lambda_1^{-1}, \dots, \lambda_p^{-1}).$$

Putting $\hat{\boldsymbol{\beta}}$ or $\hat{\boldsymbol{\xi}}$ into the Bayes Estimator $\widehat{\boldsymbol{\Sigma}}_1^B(\boldsymbol{\xi}, g)$, we obtain the empirical Bayes estimator

$$\begin{aligned} \widehat{\boldsymbol{\Sigma}}_1^B(\hat{\boldsymbol{\xi}}, g) &= \frac{1}{n_1 + n_2} S_1^{1/2} \mathbf{Q} \left\{ \text{diag}\left[\min\left\{\frac{n_2}{n_1}, \frac{1}{\lambda_i}\right\}\right]_i + \mathbf{I} \right\} \mathbf{Q}^t S_1^{1/2} A_g^* \\ &= S_1^{1/2} \mathbf{Q} \text{diag}\left[\min\left\{\frac{1}{n_1}, \frac{\lambda_i + 1}{(n_1 + n_2)\lambda_i}\right\}\right]_i \mathbf{Q}^t S_1^{1/2} A_g^*, \end{aligned}$$

where $\text{diag}[a_i]_i = \text{diag}(a_1, \dots, a_p)$. Here note that orthogonal matrices $\mathbf{P}$ and $\mathbf{Q}$ satisfy

$$\begin{cases} S_2^{-1/2} S_1 S_2^{-1/2} = (S_2^{-1/2} S_1^{1/2})(S_2^{-1/2} S_1^{1/2})^t = \mathbf{P} \boldsymbol{\Lambda} \mathbf{P}^t \\ S_1^{-1/2} S_2 S_1^{-1/2} = (S_1^{-1/2} S_2^{1/2})(S_1^{-1/2} S_2^{1/2})^t = \mathbf{Q} \boldsymbol{\Lambda}^{-1} \mathbf{Q}^t. \end{cases}$$

Then we have that

$$S_2^{-1/2} S_1^{1/2} = \mathbf{P} \boldsymbol{\Lambda}^{1/2} \mathbf{Q}^t \quad \text{or} \quad S_2^{1/2} \mathbf{P} = S_1^{1/2} \mathbf{Q} \boldsymbol{\Lambda}^{-1/2}.$$

Hence $\widehat{\boldsymbol{\Sigma}}_1^B(\hat{\boldsymbol{\xi}}, g)$ is rewritten as

$$\widehat{\boldsymbol{\Sigma}}_1^B(\hat{\boldsymbol{\xi}}, g) = S_2^{1/2} \mathbf{P} \text{diag}\left[\min\left\{\frac{\lambda_i}{n_1}, \frac{\lambda_i + 1}{n_1 + n_2}\right\}\right]_i \mathbf{P}^t S_2^{1/2} A_g^*,$$

which is identical to the REML estimator $\widehat{\boldsymbol{\Sigma}}_1^{\text{REML}}(g)$. Hence the REML estimator can be interpreted as the empirical Bayes rule.

3.3. An extension of Stein's dominance results

In estimation of a covariance matrix of a multivariate normal distribution, James and Stein (1961) established a surprising decision-theoretical result that

the unbiased estimator $n_1^{-1}S_1$ is neither minimax nor admissible. Let G_T^+ be the triangular group consisting of lower triangular matrices with positive diagonal elements. Let T_1 be a matrix in G_T^+ with $T_1 T_1^t = S_1$. Then their minimax estimator dominating $n_1^{-1}S_1$ is written in our setup as

$$(3.19) \quad \widehat{\Sigma}_1^{JS}(g) = T_1 D_m T_1^t A_g^*,$$

where A_g^* is given by (3.5) and D_m is the diagonal matrix given by $D_m = \text{diag}(d_1, \dots, d_p)$ for

$$(3.20) \quad d_i = k_i^{-1} = (n_1 + p + 1 - 2i)^{-1}, \quad i = 1, \dots, p.$$

This dominance result is verified to remain true in the ECD model.

PROPOSITION 3.2. *The estimator $\widehat{\Sigma}_1^{JS}(g)$ dominates the unbiased estimator $\widehat{\Sigma}_1^{UB}(g)$ relative to the Stein loss (3.4) and the risk function of $\widehat{\Sigma}_1^{JS}(g)$ is given by*

$$(3.21) \quad R_1(\omega, \widehat{\Sigma}_1^{JS}(g)) = E[-\log|D_m| - \log|S_1 A_g^*|].$$

PROOF. After making the transformations, we can set $\Sigma_1 = \Sigma_2 = I_p$ and write the risk function of $\widehat{\Sigma}_1^{JS}(g)$ as

$$(3.22) \quad R_1(\omega; \widehat{\Sigma}_1^{JS}(g)) = E[L(\widehat{\Sigma}_1^{JS}(g) \Sigma_1^{-1})] \\ = E[\text{tr } D_m T_1^t T_1 A_g^* - \log|D_m| - \log|S_1 A_g^*| - p].$$

Note that $\sum_{i=1}^p \sum_{j=1}^i t_{ij}^2 = \sum_{j=1}^p \sum_{i=j}^p t_{ij}^2$ for $T_1 = (t_{ij})$. Let $v_j = \sum_{i=j}^p t_{ij}^2$. Then the same arguments as used in the proof of Proposition 3.1 can show that,

$$(3.23) \quad E[T_1^t T_1] \\ = 2c \iint T_1^t T_1 t_{11}^{n_1-1} \dots t_{pp}^{n_1-p} |S_2|^{(n_2-p-1)/2} g\left(\sum_{i=1}^p \sum_{j=1}^i t_{ij}^2 + \text{tr } S_2\right) dT_1 dS_2 \\ = \frac{\int \cdot \int \text{diag}(v_1, \dots, v_p) \prod_{j=1}^p v_j^{k_j/2-1} |S_2|^{(n_2-p-1)/2} g(\sum_{j=1}^p v_j + \text{tr } S_2) \prod_j dv_j dS_2}{\int \cdot \int \prod_{j=1}^p v_j^{k_j/2-1} |S_2|^{(n_2-p-1)/2} g(\sum_{j=1}^p v_j + \text{tr } S_2) \prod_j dv_j dS_2},$$

for k_i defined by (3.20). It can be also shown that for $i = 1, \dots, p$,

$$(3.24) \quad \frac{\int \cdot \int v_i \prod_{j=1}^p v_j^{k_j/2-1} |S_2|^{(n_2-p-1)/2} g(\sum_{j=1}^p v_j + \text{tr } S_2) \prod_j dv_j dS_2}{\int \cdot \int \prod_{j=1}^p v_j^{k_j/2-1} |S_2|^{(n_2-p-1)/2} g(\sum_{j=1}^p v_j + \text{tr } S_2) \prod_j dv_j dS_2} \\ = (n_1 + p + 1 - 2i) \{p(n_1 + n_2) A_{p(n_1+n_2)}(g)\}^{-1} \\ = k_i (A_g^*)^{-1}.$$

Combining (3.22), (3.23) and (3.24) gives the risk function (3.21). Comparing the risk functions (3.7) and (3.21), we can get Proposition 3.2 by noting the inequality that $\sum_{i=1}^p \log(n_1 + p + 1 - 2i) \leq p \log n_1$, which can be easily checked. $\square \square$

It is known that the estimator $\hat{\Sigma}_1^{JS}(g)$ has a drawback that it depends on the coordinate system. Thus it will be desirable to construct orthogonally invariant estimators improving upon $\hat{\Sigma}_1^{JS}(g)$. Stein (1977) and Dey and Srinivasan (1985) obtained an orthogonally invariant and improved estimator in a multivariate normal distribution. Their estimator is written in our situation as

$$(3.25) \quad \hat{\Sigma}_1^S(g) = \hat{\Sigma}_1(\Psi^S, g) = S_2^{1/2} P \Psi^S(\Lambda) P^t S_2^{1/2} A_g^*,$$

where

$$\Psi^S(\Lambda) = \text{diag}(d_1 \lambda_1, \dots, d_p \lambda_p).$$

On the other hand, Stein (1956), Eaton (1970) and Takemura (1984) gave an orthogonally invariant and improved estimator, which is written in our problem as

$$(3.26) \quad \hat{\Sigma}_1^T(g) = S_2^{1/2} \left\{ \int_{O(p)} \Gamma U_r D_m U_r^t \Gamma^t d\Gamma \right\} S_2^{1/2} A_g^*,$$

where $O(p)$ is the group of $p \times p$ orthogonal matrices and $U_r \in G_T^+$ with $U_r U_r^t = \Gamma^t F \Gamma$ for $F = S_2^{-1/2} S_1 S_2^{-1/2} = P \Lambda P^t$. Takemura (1984) provided another expression of the form

$$(3.27) \quad \hat{\Sigma}_1^T(g) = S_2^{1/2} P \Psi^T(\Lambda) P^t S_2^{1/2} A_g^*,$$

where

$$\begin{aligned} \Psi^T(\Lambda) &= \text{diag}(\phi_1^T(\Lambda), \dots, \phi_p^T(\Lambda)), \\ (\phi_1^T(\Lambda), \dots, \phi_p^T(\Lambda))^t &= \text{diag}(\lambda_1, \dots, \lambda_p) W(\Lambda) (d_1, \dots, d_p)^t, \end{aligned}$$

for a $p \times p$ doubly stochastic matrix $W(\Lambda)$. In fact this dominance result still holds in the ECD model.

PROPOSITION 3.3. *The estimator $\hat{\Sigma}_1^{JS}(g)$ is further dominated by $\hat{\Sigma}_1^S(g)$ and $\hat{\Sigma}_1^T(g)$, which has the risk functions given by*

$$(3.28) \quad R_1(\omega, \hat{\Sigma}_1^S(g)) = E \left[2 \sum_{i>j} \frac{d_i - d_j}{\lambda_i - \lambda_j} \lambda_i - \log |D_m| - \log |S_1 A_g^*| \right],$$

$$(3.29) \quad R_1(\omega, \hat{\Sigma}_1^T(g)) = E \left[- \sum_{i=1}^p \log \left(\sum_{j=1}^p w_{ij}(\Lambda) d_j \right) - \log |S_1 A_g^*| \right],$$

where $W(\Lambda) = (w_{ij}(\Lambda))$.

PROOF. We first treat estimators of the general form $\hat{\Sigma}_1^*(\Phi, g) = S_2^{1/2} \Phi(F) S_2^{1/2} A_g^*$ for $p \times p$ positive definite matrix $\Phi(F)$. Let $\Sigma_1 = I$ and $\Sigma_2 = \Delta^{-1}$ without loss of generality. The risk function of $\hat{\Sigma}_1^*(\Phi, g)$ is expressed as

$$\begin{aligned} (3.30) \quad R_1(\omega, \hat{\Sigma}_1^*(\Phi, g)) &= E[\text{tr } \Phi(F) E[S_2 | F] A_g^* - \log |\Phi(F)| - \log |S_2 A_g^*| - p] \\ &= E[\text{tr } \Phi(F) (F + \Delta)^{-1} (n_1 + n_2) - \log |\Phi(F)| - \log |S_2 A_g^*| - p], \end{aligned}$$

where the second equality follows from (3.15). From (3.13), it is seen that $\mathbf{F}$ has a multivariate F -distribution with the density

$$(3.31) \quad (\text{const.}) |\mathbf{F}|^{(n_1-p-1)/2} / |\mathbf{F} + \mathbf{A}|^{(n_1+n_2)/2},$$

which does not depend on g . For evaluating the term $E[\text{tr } \Phi(\mathbf{F})(\mathbf{F} + \mathbf{A})^{-1}]$, we employ the F -identity of Muirhead and Verathaworn (1985):

$$(3.32) \quad E[\text{tr}(\mathbf{F} + \mathbf{A})^{-1} \mathbf{V}] = (n_1 + n_2)^{-1} E[2\text{tr}(\mathbf{D}\mathbf{V}) + (n_1 - p - 1)\text{tr}(\mathbf{F}^{-1} \mathbf{V})],$$

where $\mathbf{V} = (v_{ij}(\mathbf{F}))$ is a $p \times p$ matrix and $\mathbf{D} = (d_{ij})$ is a $p \times p$ matrix of partial derivative operators with $d_{ij} = 2^{-1}(1 + \delta_{ij})\partial/\partial f_{ij}$ for $\mathbf{F} = (f_{ij})$ and the Kronecker delta δ_{ij} .

When we consider the special form $\Phi(\mathbf{F}) = \mathbf{P}\Psi(\mathbf{A})\mathbf{P}^t$ for $\Psi(\mathbf{A}) = \text{diag}(\phi_1(\mathbf{A}), \dots, \phi_p(\mathbf{A}))$, it follows from Stein (1975) and Bilodeau and Srivastava (1992) that

$$(3.33) \quad \mathbf{D}(\mathbf{P}\Psi(\mathbf{A})\mathbf{P}^t) = \mathbf{P}\Psi^{(1)}(\mathbf{A})\mathbf{P}^t,$$

in which

$$\begin{aligned} \Psi^{(1)}(\mathbf{A}) &= \text{diag}(\phi_1^{(1)}(\mathbf{A}), \dots, \phi_p^{(1)}(\mathbf{A})), \\ \phi_i^{(1)}(\mathbf{A}) &= \frac{1}{2} \sum_{j=1, j \neq i}^p \frac{\phi_i(\mathbf{A}) - \phi_j(\mathbf{A})}{\lambda_i - \lambda_j} + \frac{\partial \phi_i(\mathbf{A})}{\partial \lambda_i}. \end{aligned}$$

Hence from (3.32) and (3.33), we get that

$$\begin{aligned} (3.34) \quad E[\text{tr}(\mathbf{F} + \mathbf{A})^{-1} \mathbf{P}\Psi^s(\mathbf{A})\mathbf{P}^t] &= (n_1 + n_2) \\ &= E\left[2 \sum_{i>j} \frac{d_i \lambda_i - d_j \lambda_j}{\lambda_i - \lambda_j} + (n_1 - p + 1) \sum_{i=1}^p d_i\right] \\ &= E\left[2 \sum_{i>j} \frac{d_i - d_j}{\lambda_i - \lambda_j} \lambda_i + \sum_{i=1}^p (n_1 + p + 1 - 2i) d_i\right] \\ &= E\left[2 \sum_{i>j} \frac{d_i - d_j}{\lambda_i - \lambda_j} \lambda_i + p\right], \end{aligned}$$

where the second equality can be verified by the equations

$$\frac{d_i \lambda_i - d_j \lambda_j}{\lambda_i - \lambda_j} = \frac{d_i - d_j}{\lambda_i - \lambda_j} \lambda_i + d_j$$

and $\sum_{i>j} d_j = \sum_{i=1}^p \sum_{j=1}^{i-1} d_j = \sum_{j=1}^p \sum_{i=j+1}^p d_j = \sum_{j=1}^p (p-j) d_j$. Combining (3.30) and (3.34) gives the risk function (3.28), which can be easily checked to be smaller than the risk of $\hat{\Sigma}_I^{JS}(g)$ given by (3.21), and the first part of Proposition 3.3 is proved.

For the second part, we first verify that the risk of $\hat{\Sigma}_I^{JS}(g)$ is equal to that of the estimator

$$(3.35) \quad \tilde{\Sigma}_I^{JS}(g) = \mathbf{S}_2^{1/2} \mathbf{U} \mathbf{D}_m \mathbf{U}^t \mathbf{S}_2^{1/2} \mathbf{A}_g^*,$$

where $\mathbf{U} \in G_T^+$ with $\mathbf{U}\mathbf{U}^t = \mathbf{F}$. In fact, from (3.30), the risk of $\hat{\Sigma}_I^{JS}(g)$ is written by

$$R_1(\omega, \tilde{\Sigma}_1^{JS}(g)) = E_{\mathcal{A}} [\text{tr } \mathbf{D}_m \mathbf{U}^t (\mathbf{F} + \mathbf{A})^{-1} \mathbf{U} (n_1 + n_2) - \log |\mathbf{D}_m| - \log |\mathbf{S}_1 \mathbf{A}_g^*| - p].$$

From Lemma 2 of Bilodeau and Srivastava (1992), we observe that

$$(3.36) \quad E_{\mathcal{A}} [\text{tr } \mathbf{D}_m \mathbf{U}^t (\mathbf{F} + \mathbf{A})^{-1} \mathbf{U}] = E_I [\text{tr } \mathbf{D}_m \mathbf{U}^t (\mathbf{F} + \mathbf{I})^{-1} \mathbf{U}] \\ = p(n_1 + n_2)^{-1},$$

which implies that $R_1(\omega, \hat{\Sigma}_1^{JS}(g)) \equiv R_1(\omega, \tilde{\Sigma}_1^{JS}(g))$. Hence from the convexity of the loss (3.4), it follows that $\hat{\Sigma}_1^T(g)$ dominates $\tilde{\Sigma}_1^{JS}(g)$. This dominance result is also verified by using the risk expression (3.29), which is derived as follows: From (3.36), we observe that

$$E[\text{tr } \Sigma_1^{-1} \hat{\Sigma}_1^T(g)] = E_{\mathcal{A}} \left[\text{tr} (\mathbf{F} + \mathbf{A})^{-1} \int_{O(p)} \mathbf{\Gamma} \mathbf{U} \mathbf{\Gamma}^t \mathbf{D}_m \mathbf{U}^t \mathbf{\Gamma}^t d\mathbf{\Gamma} \right] (n_1 + n_2) \\ = \int_{O(p)} E_{\mathcal{A}^*} [\text{tr} (\mathbf{F} + \mathbf{A}^*)^{-1} \mathbf{U} \mathbf{D}_m \mathbf{U}^t] d\mathbf{\Gamma} (n_1 + n_2) \\ = p,$$

where $\mathbf{A}^* = \mathbf{\Gamma}^t \mathbf{A} \mathbf{\Gamma}$. From this equation, we get the risk expression (3.29). Since $\mathbf{W}(\mathbf{A})$ is doubly stochastic, the concavity of $\log(\cdot)$ implies that

$$-\sum_{i=1}^p \log \left(\sum_{j=1}^p w_{ij}(\mathbf{A}) d_j \right) \leq -\sum_{j=1}^p \sum_{i=1}^p w_{ij}(\mathbf{A}) \log d_j \\ = -\log |\mathbf{D}_m|,$$

proving that $\hat{\Sigma}_1^T(g)$ dominates $\tilde{\Sigma}_1^{JS}(g)$. Therefore the proof of Proposition 3.3 is complete. $\square \square$

Takemura (1984) gave exact expressions for $\Psi^T(\mathbf{A})$ for $p=2$ and 3. However, the explicit calculation of $\mathbf{W}(\mathbf{A})$ for $p>3$ remains an intractable problem. Perron (1992) gave an approximation to $\mathbf{W}(\mathbf{A})$, say $\tilde{\mathbf{W}}(\mathbf{A})$, with a doubly stochastic property, and showed the minimaxity of the approximated estimator in the normal distribution. In the multivariate F -distribution, a similar dominance result was obtained by Bilodeau and Srivastava (1992), where the matrix $\tilde{\mathbf{W}}(\mathbf{A})$ is given componentwise by

$$\tilde{w}_{ij}(\mathbf{A}) = \frac{\text{tr}_{j-1}(\mathbf{A}_i)}{\text{tr}_{j-1}(\mathbf{A})} - \frac{\text{tr}_j(\mathbf{A}_i)}{\text{tr}_j(\mathbf{A})},$$

for

$$\text{tr}_j(\mathbf{A}) = \begin{cases} 1 & \text{if } j=0, \\ \sum_{1 \leq i_1 < \dots < i_j \leq p} \prod_{k=1}^j \lambda_{i_k} & \text{if } j=1, \dots, p, \\ 0 & \text{otherwise,} \end{cases}$$

and

$$\mathbf{A}_i = \text{diag}(\lambda_1, \dots, \lambda_{i-1}, 0, \lambda_{i+1}, \dots, \lambda_p).$$

The same arguments as in Bilodeau and Srivastava (1992) demonstrates that $\hat{\Sigma}_1^{JS}(g)$ is improved on by

$$\widehat{\Sigma}_1^P(g) = S_2^{1/2} P \Psi^P(\Lambda) P^t S_2^{1/2} A_g^*,$$

where

$$\begin{aligned} \Psi^P(\Lambda) &= \text{diag}(\phi_1^P(\Lambda), \dots, \phi_p^P(\Lambda)), \\ (\phi_1^P(\Lambda), \dots, \phi_p^P(\Lambda))^t &= \text{diag}(\lambda_1, \dots, \lambda_p) \widetilde{W}(\Lambda)(d_1, \dots, d_p)^t. \end{aligned}$$

Now, applying the truncation rule (3.11) to the estimator $\widehat{\Sigma}_1^S(g)$ yields the estimator

$$(3.37) \quad \widehat{\Sigma}_1^{STR}(g) = \widehat{\Sigma}_1([\Psi^S]^{TR}, g),$$

where

$$[\Psi^S(\Lambda)]^{TR} = \text{diag}\left(\min\left\{d_1\lambda_1, \frac{\lambda_1+1}{n_1+n_2}\right\}, \dots, \min\left\{d_p\lambda_p, \frac{\lambda_p+1}{n_1+n_2}\right\}\right).$$

Similarly we obtain the truncated estimators $\widehat{\Sigma}_1([\Psi^T]^{TR}, g)$ and $\widehat{\Sigma}_1([\Psi^P]^{TR}, g)$. From Theorem 2.1, we can get

COROLLARY 3.2. *The estimators $\widehat{\Sigma}_1^{STR}(g)$, $\widehat{\Sigma}_1([\Psi^T]^{TR}, g)$ and $\widehat{\Sigma}_1([\Psi^P]^{TR}, g)$ dominate $\widehat{\Sigma}_1^S(g)$, $\widehat{\Sigma}_1^T(g)$ and $\widehat{\Sigma}_1^P(g)$, respectively, relative to the Stein loss (3.4).*

We conclude this subsection with demonstrating further improvement on $\widehat{\Sigma}_1^{STR}(g)$. When we consider estimators of the general form

$$\widehat{\Sigma}_1(\Psi) = S_2^{1/2} P \Psi(\Lambda) P^t S_2^{1/2} A_g^*, \quad \Psi(\Lambda) = \text{diag}(\phi_1(\Lambda), \dots, \phi_p(\Lambda)),$$

it is quite natural to satisfy the condition

$$\phi_1(\Lambda) \geq \phi_2(\Lambda) \geq \dots \geq \phi_p(\Lambda) \quad \text{for any } \Lambda,$$

which is called *order-preserving* in Sheena and Takemura (1992). The estimator $\widehat{\Sigma}_1^{STR}$ do not satisfy the order-preserving condition.

We here demonstrate that non-order-preserving estimators can be improved upon by the order-preserving estimators. Let $\widehat{\Sigma}_1(\Psi, g)$ be a non-order-preserving estimator. Let $\phi_i^o(\Lambda)$ be the i -th largest element in $(\phi_1(\Lambda), \dots, \phi_p(\Lambda))$, so that $\phi_1^o(\Lambda) \geq \dots \geq \phi_p^o(\Lambda)$. Note that $(\phi_1^o, \dots, \phi_p^o)$ majorizes $(\phi_1, \dots, \phi_p)$, that is,

$$(3.38) \quad \sum_{i=1}^j \phi_i^o \geq \sum_{i=1}^j \phi_i \quad \text{for } 1 \leq j \leq p-1 \quad \text{and} \quad \sum_{i=1}^p \phi_i^o = \sum_{i=1}^p \phi_i.$$

Let $\widehat{\Sigma}_1(\Psi^o, g) = S_2^{1/2} P \Psi^o(\Lambda) P^t S_2^{1/2} A_g^*$ for $\Psi^o(\Lambda) = \text{diag}(\phi_1^o(\Lambda), \dots, \phi_p^o(\Lambda))$. Then we get

PROPOSITION 3.4. *If $P_\omega[\Psi(\Lambda) \neq \Psi^o(\Lambda)] > 0$ for some $\omega \in \Omega$, then $\widehat{\Sigma}_1(\Psi, g)$ is dominated by the order-preserving estimator $\widehat{\Sigma}_1(\Psi^o, g)$ relative to the Stein loss (3.4).*

PROOF. From (3.30), the risk difference can be written as

$$\begin{aligned}
(3.39) \quad & R_1(\omega, \widehat{\Sigma}_1(\Psi^o, g)) - R_1(\omega, \widehat{\Sigma}_1(\Psi, g)) \\
&= (n_1 + n_2) E[\text{tr}(\Psi^o(\Lambda) - \Psi(\Lambda)) \mathbf{B}^{-1}] \\
&= (n_1 + n_2) E^A \left[\sum_{i=1}^p (\phi_i^o(\Lambda) - \phi_i(\Lambda)) E[\mathbf{B}^{ii} | \Lambda] \right],
\end{aligned}$$

where $\mathbf{B} = \Lambda + \mathbf{P}^t \Theta^{-1} \mathbf{P}$, $\mathbf{B}^{ii}$ denotes the (i, i) -diagonal of $\mathbf{B}^{-1}$ and $E[\cdot | \Lambda]$ is a conditional expectation with respect to $\mathbf{P}$ given Λ . Following Sheena and Takemura (1992), we use the Abel's identity to get the equation

$$\begin{aligned}
& \sum_{i=1}^p (\phi_i^o - \phi_i) E[\mathbf{B}^{ii} | \Lambda] \\
&= (\phi_1^o - \phi_1) (E[\mathbf{B}^{11} | \Lambda] - E[\mathbf{B}^{22} | \Lambda]) \\
&\quad + (\phi_1^o + \phi_2^o - \phi_1 - \phi_2) (E[\mathbf{B}^{22} | \Lambda] - E[\mathbf{B}^{33} | \Lambda]) \\
&\quad + \cdots + (\phi_1^o + \cdots + \phi_{p-1}^o - \phi_1 - \cdots - \phi_{p-1}) (E[\mathbf{B}^{p-1, p-1} | \Lambda] - E[\mathbf{B}^{pp} | \Lambda]).
\end{aligned}$$

From Lemma 1 of Srivastava and Kubokawa (1999), we have the inequality

$$E[\mathbf{B}^{ii} | \Lambda] \leq E[\mathbf{B}^{jj} | \Lambda],$$

for $i < j$. This implies that the r.h.s. of (3.39) is negative, and Proposition 3.4 is proved. $\square \square$

Applying Proposition 3.4 to $\widehat{\Sigma}_1^{STRO}(g)$, we obtain the following order-preserving estimator improving on it, given by

$$\widehat{\Sigma}_1^{STRO}(g) = \mathbf{S}_2^{1/2} \mathbf{P} [[\Psi^S]^{TR}]^o \mathbf{P}^t \mathbf{S}_2^{1/2} A_g^*,$$

where $[[\Psi^S]^{TR}]^o = \text{diag}(\phi_1^{STRO}, \dots, \phi_p^{STRO})$ and ϕ_i^{STRO} is the i -th largest in the diagonal elements $\min\{d_i \lambda_i, (n_1 + n_2)^{-1}(\lambda_i + 1)\}$, $i = 1, \dots, p$.

3.4. Robustness of the dominance results

We discuss here the robustness of the dominance results given in Subsections 3.2 and 3.3. The results of Theorem 3.1 and Corollaries 3.1 and 3.2 employ the truncation rule (3.11), so that the same arguments as in Subsection 2.3 can be applied to establish their robustness within the classes C_0 and C_1 given by (2.24) and (2.25), where N in (2.24) is replaced with pkr .

The other type of the improvements includes Propositions 3.2, 3.3 and 3.4, which do not use the truncation rule. Since $A_g^* = 1$ in the multivariate normal distribution, we denote the estimators $\widehat{\Sigma}_1^{UB}(g)$, $\widehat{\Sigma}_1^{JS}(g)$, $\widehat{\Sigma}_1^S(g)$ and $\widehat{\Sigma}_1^T(g)$ with $A_g^* = 1$ by $\widehat{\Sigma}_1^{UB}$, $\widehat{\Sigma}_1^{JS}$, $\widehat{\Sigma}_1^S$ and $\widehat{\Sigma}_1^T$, respectively. From Propositions 3.1, 3.2 and 3.3, their risk functions in the ECD model are provided by

$$\begin{aligned}
R_1(\omega, \widehat{\Sigma}_1^{UB}) &= E[p\{(A_g^*)^{-1} - 1\} + p \log n_1 - \log |S_1|], \\
R_1(\omega, \widehat{\Sigma}_1^{JS}) &= E[p\{(A_g^*)^{-1} - 1\} - \log |\mathbf{D}_m| - \log |S_1|], \\
R_1(\omega, \widehat{\Sigma}_1^S) &= E \left[p\{(A_g^*)^{-1} - 1\} + \frac{2}{A_g^*} \sum_{i>j} \frac{d_i - d_j}{\lambda_i - \lambda_j} \lambda_i - \log |\mathbf{D}_m| - \log |S_1| \right], \\
R_1(\omega, \widehat{\Sigma}_1^T) &= E \left[p\{(A_g^*)^{-1} - 1\} - \sum_{i=1}^p \log \left(\sum_{j=1}^p w_{ij}(\Lambda) d_j \right) - \log |S_1| \right].
\end{aligned}$$

These expressions imply that the ordering in domination of the estimators is preserved in the ECD model, that is, the robust improvements hold for every $f(\cdot)$. This is related to the results of Kubokawa and Srivastava (1999) who established the robustness through the extended Stein-Haff identity. Instead of the extended Stein-Haff identity, we utilized the multivariate F -identity in Proposition 3.3 since the two statistics S_1 and S_2 are available. Also it is seen that the improvement by the order-preserving rule is robust since Proposition 3.4 was shown based on the multivariate F -distribution.

3.5. Estimation of the 'between' multivariate component of variance

We here address the problem of estimating $\Sigma_2 = \Sigma_1 + \tau \Sigma_A$ and the 'between' component Σ_A based on the canonical form (3.3) of the ECD model along the same line as in Subsection 2.2.

For the estimation of Σ_2 , similar results as in the previous subsections can be derived by exchanging the indices 1 and 2. Let $S_1^{1/2}$ be a symmetric matrix such that $S_1 = (S_1^{1/2})^2$ and let Q be an orthogonal $p \times p$ matrix such that $Q^t S_1^{-1/2} S_2 S_1^{-1/2} Q = A^{-1} = \text{diag}(\lambda_1^{-1}, \dots, \lambda_p^{-1})$, where $\lambda_1^{-1} \leq \dots \leq \lambda_p^{-1}$. The diagonal matrix A is also defined in Subsection 3.2 as $P^t S_2^{-1/2} S_1 S_2^{-1/2} P = A$, so that we note that the following relation holds:

$$(3.40) \quad S_2^{1/2} P = S_1^{1/2} Q A^{-1/2}.$$

Let $\Phi(A) = \text{diag}(\phi_1(A), \dots, \phi_p(A))$ and consider estimators of the form

$$(3.41) \quad \hat{\Sigma}_2(\Phi, g) = S_1^{1/2} Q \Phi(A) Q^t S_1^{1/2} A_g^*,$$

which is, from (3.40), represented as

$$(3.42) \quad \hat{\Sigma}_2(\Phi, g) = S_2^{1/2} P A^{1/2} \Phi(A) A^{1/2} P^t S_2^{1/2} A_g^*.$$

When estimator $\hat{\Sigma}_2$ of Σ_2 is evaluated in terms of the risk $R_2(\omega, \hat{\Sigma}_2) = E[L(\hat{\Sigma}_2, \Sigma_2)]$ for the function $L(\cdot, \cdot)$ given by (3.4), we can suppose that $\Sigma_2 = I$ and $\Sigma_1 = \Theta^{-1} = \text{diag}(\theta_1^{-1}, \dots, \theta_p^{-1})$ for $\theta_1^{-1} \leq 1, \dots, \theta_p^{-1} \leq 1$. Therefore we can apply the results directly to get the improvements on $\hat{\Sigma}_2(\Phi, g)$. The corresponding truncation rule is described as

$$(3.43) \quad \begin{aligned} \{\Phi(A)\}^{TR} &= \text{diag}(\phi_1^{TR}(A), \dots, \phi_p^{TR}(A)), \\ \phi_i^{TR}(A) &= \max\left\{\phi_i(A), \frac{\lambda_i^{-1} + 1}{n_1 + n_2}\right\}, \quad i=1, \dots, p, \end{aligned}$$

which yields the corresponding truncated estimator

$$(3.44) \quad \hat{\Sigma}_2(\{\Phi\}^{TR}, g) = S_1^{1/2} Q \text{diag}(\phi_1^{TR}(A), \dots, \phi_p^{TR}(A)) Q^t S_1^{1/2} A_g^*.$$

Similar to Theorem 2.1, we can verify that $\hat{\Sigma}_2(\{\Phi\}^{TR}, g)$ dominates $\hat{\Sigma}_2(\Phi, g)$ in terms of the risk $R_2(\omega; \hat{\Sigma}_2)$.

Using this truncation rule, we can get several truncated estimators being better than unbiased or Stein type improved estimators. For instance, applying the truncation rule $\{\Phi\}^{TR}$ to the unbiased estimator

$$\widehat{\Sigma}_2^{UB}(g) = n_2^{-1} S_2 = S_1^{1/2} Q \Phi^{UB} Q^t S_1^{1/2} A_g^*,$$

for $\Phi^{UB} = \text{diag}((n_2 \lambda_1)^{-1}, \dots, (n_2 \lambda_p)^{-1})$, we obtain the REML estimator

$$(3.45) \quad \widehat{\Sigma}_2^{REML}(g) = \widehat{\Sigma}_2(\{\Phi^{UB}\}^{TR}, g),$$

improving upon $\widehat{\Sigma}_2^{UB}(g)$, where

$$\{\Phi^{UB}\}^{TR} = \text{diag}\left(\max\left\{\frac{\lambda_1^{-1}}{n_2}, \frac{\lambda_1^{-1}+1}{n_1+n_2}\right\}, \dots, \max\left\{\frac{\lambda_p^{-1}}{n_2}, \frac{\lambda_p^{-1}+1}{n_1+n_2}\right\}\right).$$

Also the Stein type improved estimator corresponded to (3.25) for Σ_2 is given by

$$\widehat{\Sigma}_2^S(g) = \widehat{\Sigma}_2(\Phi^S, g) = S_1^{1/2} Q \Phi^S(\Lambda) Q^t S_1^{1/2} A_g^*,$$

where

$$\Phi^S(\Lambda) = \text{diag}\left(\frac{e_p}{\lambda_1}, \dots, \frac{e_1}{\lambda_p}\right),$$

for $e_i = (n_2 + p + 1 - 2i)^{-1}$. It should be noted that the order of $e_1, \dots, e_p$ in $\Phi^S(\Lambda)$ is reversed to the case of $\Psi^S(\Lambda)$ in (3.25) because $\lambda_p^{-1} \geq \dots \geq \lambda_1^{-1}$. Applying the truncation rule yields

$$(3.46) \quad \widehat{\Sigma}_2^{STR}(g) = \widehat{\Sigma}_2(\{\Phi^S\}^{TR}, g),$$

improving on $\widehat{\Sigma}_2^m(g)$, where

$$\{\Phi^S(\Lambda)\}^{TR} = \text{diag}\left(\max\left\{\frac{e_p}{\lambda_1}, \frac{\lambda_1^{-1}+1}{n_1+n_2}\right\}, \dots, \max\left\{\frac{e_1}{\lambda_p}, \frac{\lambda_p^{-1}+1}{n_1+n_2}\right\}\right).$$

We next consider the problem of estimating Σ_A through simultaneous estimation of (Σ_1, Σ_A) simultaneously relative to the loss

$$(3.47) \quad L_s(\widehat{\Sigma}_1, \widehat{\Sigma}_A; \Sigma_1, \Sigma_A) = n_1 L(\widehat{\Sigma}_1, \Sigma_1) + n_2 L(\widehat{\Sigma}_1 + r \widehat{\Sigma}_A, \Sigma_1 + r \Sigma_A),$$

for $L(\cdot, \cdot)$ given by (3.4). When Σ_1 and $\Sigma_2 = \Sigma_1 + r \Sigma_A$ are estimated by $\widehat{\Sigma}_1$ and $\widehat{\Sigma}_2$, it is quite natural to take the form $\widehat{\Sigma}_A = r^{-1}(\widehat{\Sigma}_2 - \widehat{\Sigma}_1)$ as an estimator of Σ_A . As long as such types of estimators are treated, the risk function of $(\widehat{\Sigma}_1, \widehat{\Sigma}_A)$ relative to the Kullback-Leibler loss (3.47) is written as

$$\begin{aligned} R_s(\omega; \widehat{\Sigma}_1, \widehat{\Sigma}_A) &= E_\omega[L_s(\widehat{\Sigma}_1, \widehat{\Sigma}_A; \Sigma_1, \Sigma_A)] \\ &= n_1 R_1(\omega; \widehat{\Sigma}_1) + n_2 R_2(\omega; \widehat{\Sigma}_2), \end{aligned}$$

where $\omega = (\Sigma_1, \Sigma_1 + r \Sigma_A) \in \Omega$ and

$$\begin{aligned} R_1(\omega; \widehat{\Sigma}_1) &= E_\omega[\text{tr } \widehat{\Sigma}_1 \Sigma_1^{-1} - \log |\widehat{\Sigma}_1 \Sigma_1^{-1}| - p] \\ R_2(\omega; \widehat{\Sigma}_2) &= E_\omega[\text{tr } \widehat{\Sigma}_2 \Sigma_2^{-1} - \log |\widehat{\Sigma}_2 \Sigma_2^{-1}| - p]. \end{aligned}$$

Hence we can obtain improved estimators of (Σ_1, Σ_A) by combining dominance results in estimation of Σ_1 and Σ_2 .

Combining $\widehat{\Sigma}_1([\Psi]^{TR}, g)$ given by (3.12) and $\widehat{\Sigma}_2(\{\Phi\}^{TR}, g)$ given by (3.44), and noting the expression (3.42), we get the estimator of Σ_A of the form

$$\begin{aligned}\widehat{\Sigma}_A([\Psi]^{TR}, \{\Phi\}^{TR}, g) &= r^{-1}(\widehat{\Sigma}_2([\Psi]^{TR}, g) - \widehat{\Sigma}_1(\{\Phi\}^{TR}, g)) \\ &= r^{-1}S_2^{1/2}P\{\Lambda^{1/2}\{\Phi(\Lambda)\}^{TR}\Lambda^{1/2} - [\Psi(\Lambda)]^{TR}\}P^tS_2^{1/2}A_g^*,\end{aligned}$$

where

$$\begin{aligned}(3.48) \quad &\Lambda^{1/2}\{\Phi(\Lambda)\}^{TR}\Lambda^{1/2} - [\Psi(\Lambda)]^{TR} \\ &= \text{diag}\left[\max\left\{\phi_i(\Lambda)\lambda_i, \frac{\lambda_i+1}{n_1+n_2}\right\} - \min\left\{\phi_i(\Lambda), \frac{\lambda_i+1}{n_1+n_2}\right\}\right]_i.\end{aligned}$$

In the case of combining the REML estimators $\widehat{\Sigma}_1^{REML}$ and $\widehat{\Sigma}_2^{REML}$, the i -th diagonal element in (3.48) is

$$\max\left\{\frac{1}{n_2}, \frac{\lambda_i+1}{n_1+n_2}\right\} - \min\left\{\frac{\lambda_i}{n_1}, \frac{\lambda_i+1}{n_1+n_2}\right\} = \max\left\{\frac{1}{n_2} - \frac{\lambda_i}{n_1}, 0\right\},$$

which gives the estimator

$$\begin{aligned}\widehat{\Sigma}_A^{REML}(g) &= r^{-1}(\widehat{\Sigma}_2^{MEML}(g) - \widehat{\Sigma}_1^{REML}(g)) \\ &= r^{-1}S_2^{1/2}P \text{diag}\left[\max\left\{\frac{1}{n_2} - \frac{\lambda_i}{n_1}, 0\right\}\right]_i P^tS_2^{1/2}A_g^*,\end{aligned}$$

which is n.n.d. This REML estimator of Σ_A is similar to the one proposed by Amemiya (1985). We thus get n.n.d. estimators $(\widehat{\Sigma}_1^{REML}(g), \widehat{\Sigma}_A^{REML}(g))$ improving on $(\widehat{\Sigma}_1^{UB}(g), \widehat{\Sigma}_A^{UB}(g))$ relative to the loss (3.47).

In the case of combining Stein type improved estimators $\widehat{\Sigma}_1^{STR}(g)$ and $\widehat{\Sigma}_2^{STR}(g)$, the i -th diagonal element in (3.48) is

$$\begin{aligned}&\max\left\{e_{p-i+1}, \frac{\lambda_i+1}{n_1+n_2}\right\} - \min\left\{d_i\lambda_i, \frac{\lambda_i+1}{n_1+n_2}\right\} \\ &= \max\left\{\frac{1}{n_2-(p+1-2i)} - \frac{\lambda_i}{n_1+p+1-2i}, 0\right\},\end{aligned}$$

which gives the estimator

$$\begin{aligned}\widehat{\Sigma}_A^{STR}(g) &= r^{-1}(\widehat{\Sigma}_2^{STR}(g) - \widehat{\Sigma}_1^{STR}(g)) \\ &= r^{-1}S_2^{1/2}P \text{diag}\left[\max\left\{\frac{1}{n_2-(p+1-2i)} - \frac{\lambda_i}{n_1+p+1-2i}, 0\right\}\right]_i P^tS_2^{1/2}A_g^*,\end{aligned}$$

which is also n.n.d. In the sequel we get n.n.d. estimators $(\widehat{\Sigma}_1^{STR}(g), \widehat{\Sigma}_A^{STR}(g))$ improving on $(\widehat{\Sigma}_1^S(g), \widehat{\Sigma}_A^S(g))$ in terms of the risk $R_s(\omega; \widehat{\Sigma}_1, \widehat{\Sigma}_A)$ where $\widehat{\Sigma}_A^S(g) = r^{-1}(\widehat{\Sigma}_2^S(g) - \widehat{\Sigma}_1^S(g))$. Comparing two n.n.d. estimators $\widehat{\Sigma}_A^{REML}(g)$ and $\widehat{\Sigma}_A^{STR}(g)$, we can note that for $i > (<)(p+1)/2$,

$$\frac{1}{n_2-(p+1-2i)} - \frac{\lambda_i}{n_1+p+1-2i} > (<) \frac{1}{n_2} - \frac{\lambda_i}{n_1},$$

which implies that

$$P\left[\frac{1}{n_2-(p+1-2i)} - \frac{\lambda_i}{n_1+p+1-2i} > 0\right] > (<) P\left[\frac{1}{n_2} - \frac{\lambda_i}{n_1} > 0\right].$$

Hence we cannot compare them in the sense of maximizing the probability that they are positive-definite.

For the robustness of the improvements, we can get similar conclusions by combining Subsections 2.3 and 3.4. In particular, we recall that $A_g^* \equiv 1$ for every $f(\cdot)$ in C_0 , and see that the dominance results given in this subsection are robust in C_0 .
