Note

Antihypertensive Effects of Sesamin in Humans

Sesamin, one of the lignans contained in sesame, has been considered to have medicinal effects. It has been reported that sesamin suppressed the development of hypertension in rats. In this study, using a double-blind, cross-over, placebo-controlled trial, we investigated the effect of 4-wk administration of sesamin on blood pressure (BP) in mildly hypertensive humans. Twenty-five middle-aged subjects with mild hypertension were divided into two groups, matched by age and body mass index. Twelve subjects were allocated to 4-wk intake of capsules with 60 mg sesamin per day and 13 subjects to 4-wk intake of a placebo (period 1). After a 4-wk washout period, the subjects received the alternative administration for 4 wk (period 2). BP decreased with statistical significance with the administration of sesamin (systolic: 137.6 ± 2.2 to 134.1 ± 1.7 mmHg, p = 0.044, diastolic: 87.7 ± 1.3 to 85.8 ± 1.0 mmHg, p = 0.045), but little changed with the placebo (systolic: 135.0 ± 1.8 to 135.1 ± 1.7 mmHg, diastolic: 85.9 ± 1.2 to 86.6 ± 1.2 mmHg). In conclusion, 4-wk administration of 60 mg sesamin significantly decreased BP by an average of 3.5 mmHg systolic BP and 1.9 mmHg diastolic BP. These results suggest that sesamin has an antihypertensive effect in humans. Epidemiological studies suggested that a 2–3 mmHg decrease in BP reduces the rate of cardiovascular diseases; therefore, it is considered that BP reduction achieved by sesamin may be meaningful to prevent cardiovascular diseases.

Key Words: sesamin, hypertension, double-blind, cross-over study, antihypertensive effects

Summary

Sesamin, one of the lignans contained in sesame, has been considered to have medicinal effects. It has been reported that sesamin suppressed the development of hypertension in rats. In this study, using a double-blind, cross-over, placebo-controlled trial, we investigated the effect of 4-wk administration of sesamin on blood pressure (BP) in mildly hypertensive humans. Twenty-five middle-aged subjects with mild hypertension were divided into two groups, matched by age and body mass index. Twelve subjects were allocated to 4-wk intake of capsules with 60 mg sesamin per day and 13 subjects to 4-wk intake of a placebo (period 1). After a 4-wk washout period, the subjects received the alternative administration for 4 wk (period 2). BP decreased with statistical significance with the administration of sesamin (systolic: 137.6 ± 2.2 to 134.1 ± 1.7 mmHg, p = 0.044, diastolic: 87.7 ± 1.3 to 85.8 ± 1.0 mmHg, p = 0.045), but little changed with the placebo (systolic: 135.0 ± 1.8 to 135.1 ± 1.7 mmHg, diastolic: 85.9 ± 1.2 to 86.6 ± 1.2 mmHg). In conclusion, 4-wk administration of 60 mg sesamin significantly decreased BP by an average of 3.5 mmHg systolic BP and 1.9 mmHg diastolic BP. These results suggest that sesamin has an antihypertensive effect in humans. Epidemiological studies suggested that a 2–3 mmHg decrease in BP reduces the rate of cardiovascular diseases; therefore, it is considered that BP reduction achieved by sesamin may be meaningful to prevent cardiovascular diseases.

Sesame seeds have been commonly used as a traditional health food since ancient times in Asian regions. Sesamin seeds contain not only oil and protein but also characteristic lignans, such as sesamin (0.01–1.0%) and sesamolin. Sesamin is epimerized during acid-clay bleaching in the oil refining process to form episesamin and sesamolin. Sesamin seeds contain not only oil and protein but also additional health food since ancient times in Asian regions.

It seems that sesamin was absorbed via the portal vein in the native form and metabolized to the mono- or di-catechol compound by enzymes in hepatocytes. Both metabolites had antioxidant activity in the liver and were finally conjugated with glucuronic acid by glucuronidase for excretion into bile.

Several studies have shown the biological activities of sesamin: anti-oxidative activity (2, 3); cholesterol and lipid-lowering (4–8); protection against liver damage (8–10); synergy with α-tocopherol (6, 11) and improvement in the bioavailability of γ-tocopherol (12–14); anticarcinogenic activities (15, 16); and precursors of mammalian lignans (17, 18). It has been also reported that sesamin suppressed the development of hypertension in rats (2, 19–26).

There are also clinical studies about the effects of sesamin in humans. Hirata et al. (5) showed that, in males with hypercholesterolemia, oral administration of 9 capsules (each capsule contained 3.6 mg sesamin and 18 mg vitamin E) per day for 4 wk, followed by 18 capsules per day for 4 wk significantly reduced serum total and LDL cholesterol levels. Kiso (8) reported that 36 mg sesamin 2 h before high intensity exercise suppressed the rise in plasma lipid peroxide levels significantly in 7 male college students. Moritani et al. (27) demonstrated that oral intake of sesamin before smoking in male college students reduced the adverse effects of smoking on the cardiac autonomic nervous system.

However, to our knowledge, there are no data showing the effects of sesamin on blood pressure in humans. In this study, using a double-blind, cross-over, placebo-controlled method, we investigated the effect of 4-wk administration of sesamin on blood pressure in mildly hypertensive humans.

Methods

Subjects. Twenty-five middle-aged subjects with mild hypertension (23 men and 2 women, age 49.1 ± 1.8 y, body mass index (BMI) 24.6 ± 0.4 kg/m², systolic pressure 137.3 ± 1.9 mmHg, diastolic pressure 87.3 ± 1.2 mmHg) were recruited from the general population.
Declaration of Helsinki. The study was approved by the ethics committee of NTT West Kyoto Hospital. Written consent was obtained. This study was approved by the ethics committee of NTT West Kyoto Hospital. The subjects had no diseases except mild hypertension, no secondary cause of hypertension, and no medication or dietary supplements that affected blood pressure. Before entering the study, the subjects were told about the nature of the study and written consent was obtained. This study was approved by the ethics committee of NTT West Kyoto Hospital and was performed in accordance with the Helsinki Declaration of 1975 (revised in 1983).

**Study design.** A double-blind, placebo-controlled cross-over study was undertaken. The subjects were divided into two groups, matched by age, BMI and systolic and diastolic blood pressures (BP). Clinical characteristics of each group of subjects at baseline are given in Table 1. There were no significant changes in age, BMI or systolic and diastolic BP between the groups.

For administration period 1 (September to October), 12 subjects (Group A) were allocated to 4-wk intake of capsules with sesamin and 13 subjects (Group B) to 4-wk intake of a placebo. After a 4-wk wash-out period, the subjects received the alternative administration for an additional 4 wk (November to December) as administration period 2. The subjects reported to the hospital five times to have the BP and body weight measured, before and after administration periods 1 and 2, and subsequently 4 wk after the end of administration period 2.

Sesamin capsules were prepared as a mixture of sesamin and episesamin at about a 1:1 molar ratio (purity 97.2%, and the remainder was other sesame contents, such as other lignans and sterols) (LOT No. 020904), provided by Suntory Ltd. (Osaka, Japan). Each sesamin capsule contained 10 mg sesamin and 180 mg wheat germ oil. The placebo capsule contained only 180 mg wheat germ oil. Capsules containing sesamin and the placebo were the same shape and color, and both subjects and investigators were blinded as to the composition of the capsules. Group A and Group B subjects took 3 capsules twice per day with water after breakfast and dinner during the administration periods. The subjects were instructed not to change their diets (including meal times and salt intake) or exercise routines throughout this study.

**Measurement of body weight and blood pressure.** After an overnight fast, body weight and blood pressure were measured. BP was recorded at 10 a.m. after 30 minutes’ rest, using a mercury sphygmomanometer (BP-203RVIII, Japan Colin Limited, Tokyo, Japan) on the right upper arm in the sitting position. We recorded BP several times and adopted the average of three measurements after almost stable BP.

**Statistical analysis.** Data are expressed as the means ± SE. The unpaired t-test was used to compare subjects in Group A and B in terms of baseline characteristics. The paired t-test was used to compare BP before and after the administration periods. Repeated analyses of covariance were used to compare the BMIs and changes in BP. p < 0.05 was considered significant. The statistical software StatView 5.0 (SAS Institute Inc., NC, USA) was used for analyses.

**Results**

Throughout the study, no significant complaints or side effects were induced by sesamin. The average BMI of the subjects did not change significantly from the beginning of period 1 to the end of period 2 in either Group A or B (p = 0.13, 0.29, respectively). Figure 2 shows the changes in the average BP levels throughout this study. In Group A (solid line), systolic and diastolic BP after administration of sesamin were significantly decreased compared with before administration in period 1 (p = 0.04, 0.04, respectively). After the 4-wk washout, systolic and diastolic BP were slightly increased and after administration of the placebo in the period 2. BP was also increased. Meanwhile, in Group B (broken line), systolic and diastolic BP after administration of the placebo was slightly decreased in period 1, but this was not significant (p = 0.49, 0.74, respectively). After the washout, BP was slightly increased, but subsequently decreased after period 2, but not significantly (p = 0.43, 0.30, respectively). After the 4-wk washout from period 2, BP increased in both groups. Figure 3 shows the changes in BP in the sesamin and placebo groups throughout the study. The mean decreased levels of BP following the administration of sesamin were 3.5 mmHg systolic BP and 1.9 mmHg diastolic BP (systolic: 137.6 ± 2.2 to 134.1 ± 1.7 mmHg, p = 0.044, diastolic: 87.7 ± 1.3 to 85.8 ± 1.0 mmHg, p = 0.045); however, they were little changed by the placebo (systolic: 135.0 ± 1.8 to 135.1 ± 1.7 mmHg, p = 0.92, diastolic: 85.9 ± 1.2 to 86.6 ± 1.2 mmHg, p =

0.48), and the collective data showed that BP was significantly decreased by the administration of sesamin. After the 4-wk washout from the end of period 2, the average BP in the sesamin group increased to almost the baseline BP.

**Discussion**

In this study, we explored the possible hypotensive effect of sesamin in humans. Our study revealed that 4-wk administration of 60 mg sesamin caused a decrease in BP with an average of 3.5 mmHg for systolic BP and 1.9 mmHg for diastolic BP. To our knowledge, this is the first study to investigate the antihypertensive effect of sesamin in humans.

Epidemiological studies suggested that a slight decrease in BP reduces the rate of cardiovascular diseases. The INTERSALT study reported that a 2–3 mmHg decrease in systolic BP is associated with a 4% lower risk of coronary death and a 6% lower risk of stroke death in middle age in the US and UK (28). It was also reported that a 2 mmHg decrease in systolic BP is associated with a 6.4% lower risk of mortality due to cerebral vessel disease in Japan (29); therefore, it is considered that the BP reduction achieved by sesamin in
this study may be meaningful to prevent cardiovascular diseases.

In period 2, BP was decreased in Group B (sesamin administration) but not significantly, compared with the significant decrease in Group A in period 1. Considering the increased BP levels of Group A at the end of period 2 (placebo) in winter (November to December), the relative cardiovascular load in winter could elevate BP and cause a bias against the hypotensive effect of sesamin.

Previous studies reported the biophysical mechanism of the antihypertensive effect of sesamin and its metabolites in rats. Sesamin ameliorated the development of deoxycorticosterone acetate (DOCA)-salt-induced vascular hypertrophy and prevented the development of hypertension and cardiac hypertrophy in two-kidney, one-clip hypertensive rats (20), and delayed the development of hypertension and ameliorated both vascular hypertrophy and renal damage in salt-loaded stroke-prone spontaneously hypertensive rats (21). Accumulating evidence indicates that oxidative stress, especially increased \( \text{O}_2^- \) production, is closely related to the development of hypertension (30) and it is suggested that the mechanism of the antihypertensive effects of sesamin is its antioxidative activities and, in part, sesamin improved impaired endothelium-dependent vasodilatory responses and vasorelaxation (23, 24, 31). It is also thought that sesamin may improve hypertension by its ability to induce nitric oxide and inhibit endothelin-1 production from human umbilical vein endothelial cells (25). Furthermore, it is suggested that the metabolic products had potent radical-scavenging activities in vitro (2) and that the enhancement of endothelium-dependent vasorelaxation induced by sesamin metabolites is one of the important mechanisms of the in vivo antihypertensive effect of sesamin (31). Taken together, it is considered that sesamin might involve several pathways in its hypotensive effects (26).

We used sesamin as a mixture of sesamin and episesamin. It has been noted that, compared with sesamin, episesamin is more competent in increasing the activity of gamma-tocopherol metabolism by its ability to induce nitric oxide and inhibit endothelin-1 production from human umbilical vein endothelial cells (25). Furthermore, it is suggested that the metabolic products had potent radical-scavenging activities in vitro (2) and that the enhancement of endothelium-dependent vasorelaxation induced by sesamin metabolites is one of the important mechanisms of the in vivo antihypertensive effect of sesamin (31). Taken together, it is considered that sesamin might involve several pathways in its hypotensive effects (26).
