(Received January 24, 1994)

Summary Mice fed a *Spirulina platensis* diet showed increased numbers of splenic antibody-producing cells in the primary immune response to sheep red blood cells (SRBC). However, immunoglobulin G (IgG)-antibody production in the secondary immune response was hardly affected. The percentage of phagocytic cells in peritoneal macrophages from the mice fed *S. platensis* diet, as well as the proliferation of spleen cells by either concanavalin A (Con A) or phytohemagglutinin (PHA) was significantly increased. Addition of a hot-water extract of *S. platensis* (SHW) to an in vitro culture of spleen cells markedly increased proliferation of these cells, whereas culture of thymus cells was scarcely affected. The *Spirulina* extract also significantly enhanced interleukin-1 (IL-1) production from peritoneal macrophages. Addition to the in vitro spleen cell culture of SHW as well as the supernatant of macrophages stimulated with SHW resulted in enhancement of antibody production, that is, an increase of the number of PFC. These results suggest that *Spirulina* enhances the immune response, particularly the primary response, by stimulating macrophage functions, phagocytosis, and IL-1 production.

**Key words** *Spirulina platensis*, antibody production, macrophage, phagocytosis, interleukin 1

*Spirulina platensis*, which belongs to the group cyanobacteria (blue-green algae), has been used for over a thousand years as a source of food because of its high protein content and good amino acid composition (1–3). As a result of mass cultivation of *S. platensis* in synthetic medium (4), it has become possible to provide it as a food material. In addition to the claim of safety and health benefits, there are many reports concerning the effectiveness of *Spirulina* in reducing hypercholesterolemia (5,6). Furthermore, some reports have shown that *S. platensis* may be beneficial in treating some forms of atopic bronchial asthma and cancer involving...
immune functions (7, 8). It is therefore of interest from the nutritional and medical points of view to investigate whether *S. platensis* affects immunological indices in humans and animals.

In the present paper, we have used *in vivo* and *in vitro* systems to demonstrate that *S. platensis* and its extracts enhance the immune response through the enhancement of macrophage function in mice.

**MATERIALS AND METHODS**

*Animals.* Male inbred BALB/cAnNCrj and C57BL/6NCrj mice aged 4 weeks (Charles River Japan Inc., Japan) were used. Mice were housed 5 per polycarbonate cage (W21 × D33 × H13 cm) with wood-flake bedding. They were divided into three groups, Control, SP-10, and SP-20, and were kept in a constant temperature (25 ± 1°C) and relative humidity (60 ± 5%) with a 12-h light period from 08:00 to 20:00 h. Mice in the control group were fed normal laboratory chow, CE-2 (Clea Japan Inc., Japan), whereas mice in the experimental groups, SP-10 and SP-20, received CE-2 containing 10 and 20% (w/w) dried *S. platensis*, respectively. Energy, protein, and other basal nutrients in these chows were not adjusted. The nutritional composition of *S. platensis* and the laboratory chow, CE-2 is shown in Table 1. Food and water were given ad libitum. Body weight and consumption of food and water were measured twice a week during the experiments.

*Immunization and assay for immune response to SRBC.* Immune responses to sheep red blood cells (SRBC) were determined by immunizing BALB/cAnNCrj mice intraperitoneally with 0.2 ml of SRBC suspension per 10 g body weight as the primary immunization at 7 weeks after the beginning of feeding in each dietary group. Secondary immunization was performed 14 days after the primary immunization. Ten mice from each dietary group were killed 4 days after either primary or secondary immunization for the assay because it was considered to be the time when the immune responses reached a maximum (9). Mice in each dietary group were exsanguinated from the femoral artery under ether anesthesia, and the serum

sample was obtained by centrifugation at 1,500×g. To determine the number of splenic plaque-forming cells (PFC), a modified Jerne's plaque assay described by Cunningham and Szenberg (10) was performed (direct PFCs). To detect indirect PFCs in the secondary response, anti-mouse IgG rabbit serum was used in the plaque assay as described in the method of Sterzl and Riha (11). The number of IgG-antibody producing cells (IgG-PFC) were expressed as PFCs obtained by subtracting the number of direct PFCs from that of indirect PFCs. Hemagglutination (HA) titers in the sera with or without 2-mercaptoethanol (2-ME) treatment were measured as described previously (9).

Mitogen-induced proliferation of spleen cells. Spleen cells individually obtained from 10 BALB/cAnNCrj mice of each dietary group were suspended in RPMI-1640 supplemented with 10% fetal calf serum (FCS, GIBCO Lab., NY) and 2-ME (0.05 mM), and cultured at a density of 5×10^5/ml/well by using 96-well tissue culture plates in triplicate for 72 h with varying concentrations of Concanavalin A (Con A; E.Y Lab. Inc., CA), Phytohemagglutinin-p (PHA-p; Difco Laboratories, MI), or Lipopolysaccharide E. coli 055:B5 (LPS; Difco Laboratories, MI). Cell proliferation was assayed by colorimetric MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide; Sigma Chemical Co., MO) method, that is, 10 μl of stock MTT (5 mg/ml) was added to each well and incubated for the last 4 h. Acid-isopropanol was then added to all wells to dissolve the generated dark-blue crystals, and the absorbance was read on a microplate reader MTP-120 (Corona Electric Co., Japan) at 570 nm (12). Values are expressed as means of 10 mice from each group.

Phagocytosis in peritoneal macrophages. The peritoneal exudate cells (PEC) were obtained from 10 BALB/cAnNCrj mice of each dietary group by washing the abdominal cavity with Hank's balanced salt solution (HBSS) without stimulation. Adherent cells on cover slips obtained from the PEC (1×10^6 cells/ml) of each mouse were used to examine phagocytic activity. Cells which ingested more than 4 latex particles (1.02 μm diameter; Sigma Chemical Co., MO) out of 200 adherent cells were counted after being stained with Giemsa solution (13). Values are expressed as M±SD of 10 mice from each group.

Hot-water extraction of Spirulina. Spray-dried powder of S. platensis (30 g) obtained from Dainippon Ink & Chemicals Inc. (Ichihara, Japan) was extracted with 300 ml of boiling water for 1 h. The supernatant of the extract separated by centrifugation for 10 min at 8,000 rpm twice was freeze-dried to obtain pale blue-green powder (8.22 g), which was designated as SHW.

Mitogenic activity of hot-water extract of Spirulina (SHW). Spleen and thymus were obtained from 5 mice (C57BL/6NCrj) after exsanguination under ether anesthesia. Either spleen or thymus cells were suspended in RPMI-1640 supplemented with 10% FCS and 2-ME, and cultured at a density of 5×10^5 cells/0.1 ml/well using 96-well tissue culture plates with 10 μl/well of SHW in Eagle's minimum essential medium for 72 h. Proliferation of the cells was measured by the colorimetric MTT method as described above.
Induction of IL-1 from peritoneal macrophages by SHW. PEC collected together from 5 mice (BALB/cAnNCrj) which were stimulated by intraperitoneal injection of 4% glycogen, were suspended in RPMI-1640 supplemented with 10% FCS and incubated at a density of 1×10^6 cells/ml/well using 24-well tissue culture plates. One hour after incubation, the medium was changed to RPMI-1640 supplemented with 1% FCS after washing the wells to remove non-adherent cells. Adherent cells were further incubated in triplicate for 24 h with or without SHW for induction of IL-1. The supernatants of adherent cells, i.e., conditioned medium (CM), 0-CM (without SHW as a control), and SHW-CM, respectively, were filtered through a 0.2-µm-pore filter to remove cells and sterilize them. They were then measured for IL-1 activity as follows: C3H/HeJ Jcl (male, 4–6 week-old; Clea Japan Inc., Japan) thymocytes (1.5×10^6 cells/0.1 ml of medium) were cultured with the CM in the presence of PHA (50 µg/ml in final concentration) in 96-well tissue culture plates for 72 h (14) and the thymocyte proliferation was measured by the colorimetric MTT method.

Antibody production in spleen cells following in vitro culture with SHW. Spleen cells obtained from 3 mice (C57BL/6NCrj) were suspended in RPMI-1640 supplemented with 10% FCS and 2-ME at a density of 1×10^6 cells/ml. The cell suspension (0.5 ml per well) was cultured using 24-well tissue culture plates in triplicate with 0.5 ml of SRBC suspension (10×10^6 cells/ml) as an antigen and 50 µl of SHW or SHW-CM as a test substance for 4 days. The number of antibody-forming cells (direct PFC) in an aliquot of the cultured cell suspension was measured as described above and expressed as the number of PFC per well.

Statistical analysis. Statistical analysis of data was performed by Student's t-test. The level of significance was set at p<0.05.

RESULTS

The experimental groups of BALB/cAnNCrj mice fed Spirulina diets (SP-10 and SP-20) gained the same amount of weight (Fig. 1) and consumed an equivalent amount of food and water compared to the mice in the control group.

Humoral immune responses to SRBC

In primary immune response to SRBC, significant increase of the splenic PFCs per 10^6 cells was observed in mice fed Spirulina diets (SP-10 and SP-20), as compared to the control group. However, HA titers observed in SP-10 and SP-20 were almost the same as the control group (Table 2). In the secondary immune response, neither the number of IgG-PFC nor HA titers in the sera treated with 2-ME was affected, although HA titer without 2-ME treatment in SP-10 was significantly higher than that in the control group.

Mitogen-induced proliferation of spleen cells

As shown in Fig. 2A and B, the proliferation of spleen cells with T-cell

mitogens, Con A and PHA was significantly higher in the mice fed diets containing *Spirulina* than that of mice in the control group. The effect was greater using PHA (2.5 μg/ml) and Con A (50–100 μg/ml). Conversely, the mitogenicity of the spleen cells by LPS (B-cell mitogen) showed no differences among the dietary groups (Fig. 2C).

**Phagocytosis of latex particles in peritoneal macrophages**

The number of PEC obtained from the mice in the SP-20 group tended to be higher than that from the control group (Table 3). The percentage of phagocytic cells in peritoneal macrophages was significantly higher in the SP-10 group than in the control group ($p < 0.05$) (Table 3).

**Proliferative response of spleen or thymus cells to SHW**

Direct proliferative response of spleen or thymus cells showed that SHW increased the proliferation of spleen cells significantly and dose-dependently, without significantly affecting thymocyte proliferation (Fig. 3).

**IL-1 production in peritoneal macrophages by SHW**

Peritoneal macrophages obtained from the PEC of BALB/cAnNCrj mice as adherent cells were incubated with or without SHW for induction of IL-1 activity in the conditioned medium (CM). As shown in Fig. 4, IL-1 activity of SHW-CM was significantly higher (p<0.05) than that of 0-CM.

SRBC as an antigen to induce antibody-forming cells. The number of PFC per well measured as antibody-forming cells was significantly increased by incubation with 50 µg/ml of SHW (Fig. 5), as well as with SHW-CM which showed a significant increase in IL-1 production.

DISCUSSION

In primary immune responses to SRBC, a thymus-dependent antigen, the number of splenic antibody-producing cells increased significantly in mice fed diets containing Spirulina (Table 2). HA antibody titers observed in the SP-10 and SP-20 groups, however, were almost the same as the control group. IgG-antibody response in the secondary immune response was hardly affected, except for HA titer without 2-ME treatment, suggesting that Spirulina affects IgM antibody synthesis in the initial phase of the immune response rather than IgG antibody synthesis in the latter or secondary response. The percentage of phagocytic cells in peritoneal macrophages from the mice fed diets containing Spirulina, in addition to the number of PEC, was significantly increased (Table 3). Furthermore, the higher enhancement of spleen cell proliferation by T-cell mitogens (Con A and PHA) was observed in the mice fed diets containing Spirulina, whereas the mitogenic activity with LPS (a B-cell mitogen) was not different among the dietary groups (Fig. 2). To confirm the results of the in vivo study, we then conducted in vitro experiments and observed the effects of the hot-water extract of Spirulina (SHW) on the spleen-
or thymus-cell proliferation and on macrophage function. As shown in Fig. 3, proliferation of spleen cells was markedly increased when SHW was directly added to the culture, whereas thymus cells were scarcely affected. The *Spirulina* extract also significantly enhanced the production of IL-1 in peritoneal macrophages (Fig. 4). Furthermore, adding 50 μg/ml of SHW itself as well as the SHW-CM increased antibody production in the *in vitro* spleen cell culture (Fig. 5). The concentration (5 μg/ml of SHW), however, was too low to enhance the PFC response. Since the calculated concentration of SHW in the SHW-CM was 5 μg/ml, the increase of the number of PFC by the SHW-CM might result from a factor(s) other than SHW such as IL 1. These results suggest that *Spirulina* affects macrophage functions mainly in terms of phagocytosis and IL-1 production, and that it may subsequently act on the proliferation of T cells in the spleen, contributing to the enhancement of the immune responses, particularly the primary response. Recently, it was reported that intraperitoneally injected polysaccharides of *Spirulina* increased the percentage of phagocytic cells in peritoneal macrophages in addition to the hemolysin content in the blood of mice (15). Macrophages from chickens exposed to water-soluble extract of *Spirulina* in culture medium also showed on increase in the percentage of phagocytic cells as well as in the number of internalized unopsonized SRBC per phagocytic cell (Qureshi, M. A., personal communication). The percentage of phagocytic macrophages in chicken capable of engulfing opsonized SRBC was, however, not affected by the *Spirulina* extract. To evaluate the relation of antibody production and macrophage function in mice, the specific phagocytic function mediated by Fc receptors should be further investigated.

It is known that protein content in *S. platensis* is relatively high (55–70%) (2). The compounded chows containing dried *S. platensis* which were used in *in vivo* study contained 1.1–1.3 times as much protein as normal laboratory chow, CE-2 (Table 1). Hot-water extract of *S. platensis* which was used in the *in vitro* study contained 36.3% protein and 10% polysaccharide, measured by the methods of Kjeldahl and phenol-sulfuric acid, respectively (data not shown). It is not evident at present whether the enhancement of antibody production *in vivo* and the increase of IL-1 activity in macrophages, as well as the proliferation and antibody production in *in vitro* spleen cell culture, are due to nutritional improvement by high protein content of dietary *Spirulina* or to specific component(s) in the hot-water extract of *Spirulina*, such as protein or polysaccharide.

It is suggested from the result of limited thymus-cell proliferation by the *Spirulina* extract (Fig. 3) that *Spirulina* may not affect T-cell function directly. Nevertheless, Nagao et al. (16) reported that delayed-type hypersensitivity (DTH) reaction by toluene-2,4-diisocyanate in mice treated with *Spirulina* diet for 5 weeks was significantly suppressed in the exercise and no exercise groups. It is not clear which process in the DTH reaction *Spirulina* affects; induction of effector and suppressor cells or expression of local inflammatory events by various cytokines from T cells and macrophages (17,18). It is necessary to investigate further the direct effects of *Spirulina* on both T- and B-cell functions.
Based on the results of the present study, it is suggested that *Spirulina* and its extract may enhance immune function through the modulation of macrophage function. For a better understanding of the beneficial effects of *Spirulina*, more extensive studies need to be done concerning macrophage function including antitumor activity, and identification of the active component of *Spirulina*. Such studies are currently in progress in our laboratory.
