(Received March 10, 1998)

Summary A sandwich enzyme-linked immunosorbent assay for the soybean allergen, which consists of a monoclonal antibody (D4) as the fixing (first) antibody and another peroxidase-conjugated monoclonal antibody (C5) as the second, has been developed. Both D4 and C5 monoclonal antibodies strongly bound to the guanidine/HCl-denatured allergen, Gly m Bd 28K. Therefore the samples used in the present experiment were extracted with sodium phosphate buffer (pH 8.0) containing 6M guanidine and 10mM 2-mercaptoethanol, then completely dialyzed against phosphate-buffered saline (PBS). The dialyzed samples were subjected to the assay. Various soybean products were observed to contain the allergen at high concentrations, such as soybean protein isolate (SPI), tofu, kori-dofu, and yuba, but its contents in soy milk and abura-age were found to be low. In fermented products such as natto, soy sauce, and miso, and even in the processed foods with soybean protein isolate (SPI), the allergen was not detected. These results were also confirmed by an immunoblotting technique with D4.

Key Words soybean, soybean allergen, Gly m Bd 28K, sandwich enzyme-linked immunosorbent assay

Soybean is a major protein source in Japanese food, and it is also known to be a representative allergic food causing such syndromes as atopic dermatitis. We systematically investigated allergens in soybeans and showed that Gly m Bd 68K (α-subunit of β-conglycinin), Gly m Bd 30K (34kDa-oil-body-associated protein), and Gly m Bd 28K are the major allergens in soybean seeds (2). Gly m Bd 68K

and Gly m Bd 30K have been studied (2–4). Gly m Bd 28K has recently been purified by use of a monoclonal antibody (mAb, C5) against the allergen and characterized (1). For the development of hypoallergenic soybean products, the establishment of an analytical method to determine their allergen contents and their characterization are inevitable. We therefore prepared two mAbs against Gly m Bd 30K and used them to develop a sandwich enzyme-linked immunosorbent assay (ELISA) for Gly m Bd 30K (5). However, no analytical method for Gly m Bd 28K, one of the main allergens, has been established.

In this report, we describe the development of a sandwich ELISA for Gly m Bd 28K. Furthermore, the amounts of the allergen in various soybean products were measured by the sandwich ELISA.

MATERIALS AND METHODS

Materials. The materials used in the present study were obtained from the sources indicated: mouse myeloma cell line, P3 × 63Ag8U1 (P3U1) (Shino Test Institute, Sagamihara, Japan); BALB/c mice (SLC, Shizuoka, Japan); complete and incomplete Freund’s adjuvant (Nakalai Tesque, Kyoto, Japan); fetal bovine serum, sterilized L-glutamine and streptomycin-penicillin mixture (MA Bioproducts, CA, USA); RPMI 1640 (Nissui Pharmaceutical, Tokyo, Japan); a mouse monoclonal antibody isotyping kit (Amersham International PLC, Amersham, UK); aminopterin (Sigma, MO, USA); polyethylene glycol 4000 (Merck, Darmstadt, Germany); prepared protein A column and nitrocellulose membrane (Bio-Rad, CA, USA); lysyl endopeptidase from Achromobacter lyticus M 497-1 (Promega, Madison, WI, USA); peroxidase-conjugated sheep anti-mouse IgG and IgM (Organon Teknika, West Chester, PA, USA); mouse IgG (Zymed Laboratories, CA, USA); mouse IgM (Bethyl, Montgomery, TX, USA); electrophoresis calibration kit (Pharmacia, Uppsala, Sweden); defatted soybean flakes and soybean protein isolate (SPI) (Fuji Oil, Osaka, Japan).

Preparation of Gly m Bd 28K. Gly m Bd 28K was prepared in the same manner as described earlier (1). Briefly, proteins in defatted flakes were extracted with 10 mM Tris-HCl buffer (pH 8.0), and 7S globulin fraction was then obtained. The 7S globulin proteins were fractionated with ammonium sulfate. The precipitate formed from 50% to 70% saturation was dialyzed against 10 mM Tris-HCl buffer (pH 8.0). The dialysate was subjected to affinity (C5-Sepharose), ion-exchange (DEAE-Sepharose 6B), and gel-filtration (Sephacryl S-200) chromatographies, successively. The purified allergen obtained as described above was shown to be homogenous on SDS-PAGE. The allergen was used as the antigen or the authentic Gly m Bd 28K in this work.

Preparation of mAb. One of the two mAbs against Gly m Bd 28K used for the present sandwich ELISA, C5, had been obtained previously (1). To develop a sandwich ELISA for Gly m Bd 28K, another mAb had to be produced. Therefore a hybridoma producing a suitable mAb for the sandwich ELISA was prepared in
the same manner as described earlier (6), except that the antigen was used instead of the partially purified allergen. The hybridoma obtained was intraperitoneally injected into female BALB/c mice primed with pristane. After 10 to 14 d, the ascitic fluids that had formed were collected. The mAb was partially purified from the ascitic fluids by precipitation with ammonium sulfate (0–50% saturation). This mAb was named D4 and used in the present study.

**Binding of the mAbs to the allergen.** The purified allergen was denatured by dialysis at 4°C overnight against 50 mM potassium phosphate buffer (pH 8.0) containing 6 M guanidine and 10 mM 2-mercaptoethanol, followed by dialysis against phosphate-buffered saline (PBS). One hundred microliters of the dialysate obtained (15 μg/mL) was added to the wells of a 96-well microplate and incubated at 37°C for 2 h. After being blocked with 1% gelatin in PBS and washing with PBS, the proteins on the well were treated with various concentrations of C5 or D4. C5 or D4 bound to the allergen was reacted with peroxidase-conjugated anti-mouse IgG or IgM, respectively. The immunocomplexes formed on the wells were incubated for 30 min at room temperature with O-phenylenediamine (0.4 mg/mL) and 0.01% H₂O₂ in 25 mM citrate/phosphate buffer (pH 5.0), and the absorbances of the reaction mixtures in the wells at 492 nm were determined with a microplate reader Model 450 (Bio-Rad).

**Preparation of samples for sandwich enzyme-linked immunosorbent assay (ELISA).** Soybean seeds, soybean products, or processed foods including SPI (2 g or 10 g) were homogenized in 50 mL of 50 mM sodium phosphate buffer (pH 8.0) containing 6 M guanidine and 10 mM 2-mercaptoethanol (buffer A) with a Polytron homogenizer and centrifuged at 10,000 × g for 30 min. The precipitates were washed three times with the same buffer. These supernatants were combined and used as samples for the sandwich ELISA. The samples were shown to contain only a small amount of the allergen, but a high concentration of the other proteins, which were considered to interfere with a precise assay of the allergen. Therefore a bulk interfering protein was removed from the sample with a gel filtration. To determine the elution profile of the allergen, the purified allergen mixed with soybean extract was subjected to a Sephacryl S-200 column (ϕ1.1 × 65 cm) and eluted with buffer A. The allergen in each fraction was detected with the sandwich ELISA, and the fractions containing the allergen (fraction No. 23–27, 1 mL/fraction) were pooled and concentrated by ultrafiltration through a Diaflo YM1 membrane filter. The concentrate was then dialyzed against PBS overnight at 4°C. The samples to be analyzed were chromatographed and treated under the same conditions described above, then used for the ELISA experiment.

**Sandwich ELISA.** Peroxidase-conjugated C5 used in the sandwich ELISA system for the allergen was prepared according to the method of Nakane and Kawaoi (7). One hundred microliters of D4 (25 μg/mL) were added to the wells of a 96-well microplate and incubated at 37°C for 2 h. The wells were blocked with 1% gelatin in PBS at 37°C for 1 h, then washed three times with PBS. The wells were incubated with the extracts at 37°C for 1 h and washed three times with PBS.
containing 0.05% Tween 20 (PBS/Tween). The allergen bound to D4 on the wells was further reacted with peroxidase-conjugated C5 (16.4 μg/mL). The immunocomplexes on the wells were analyzed as mentioned above.

**Sodium dodecyl sulfate-poly acrylamide gel electrophoresis (SDS-PAGE) and immunoblotting.** In this experiment, the buffer used for the preparation of the sample contained 6 M guanidine, which is known to react with SDS in electrode buffer to form SDS-guanidine complex and the complex precipitates. Therefore guanidine in the sample was removed by dialysis against PBS containing 6 M urea and 10 mM 2-mercaptoethanol. A dialyzed sample solution was mixed with an equal volume of the sample buffer, and the mixture was heated for 5 min in a boiling water bath. The sample prepared was applied on a 15% polyacrylamide gel. After SDS-PAGE, the proteins separated on the gel were electrophoretically transferred onto nitrocellulose membrane. The membrane was blocked with 1% BSA in 20 mM Tris-HCl buffer (pH 7.4) containing 0.15 M NaCl and 0.05% Tween 20 and incubated at 37°C for 1 h with D4. The bound D4 (IgM) was reacted with peroxidase-conjugated sheep antimouse IgM. The immunocomplexes on the membranes were detected by a 30-min incubation at room temperature with 4-chloro-1-naphthol and H₂O₂ as the substrates. The immunoblotting of the products obtained by the lysyl endopeptidase digestion was done as follows. Intact allergen (30 μg) was digested at 30°C for 5 h with lysyl endopeptidase (1:100 lysyl endopeptidase to the allergen, by weight), as described in a previous paper (8). The proteolytic products were applied to SDS-PAGE and electrophoretically transferred onto nitrocellulose membrane, as described above. The peptides on the membrane were immunoblotted with C5 or D4. The bound C5 or D4 was reacted with peroxidase-conjugated sheep anti-mouse IgG or anti-mouse IgM and assayed by the same manner as described above.

**RESULTS AND DISCUSSION**

**Preparation of mAb**

The mAb C5 had been prepared and characterized in the previous paper (1). Its light chains were κ, and the heavy chains were γ1 (IgG1). A cell line producing another mAb (D4) against the allergen has been established in the present study. The light and heavy chains of D4 were κ and μ, respectively (IgM). Both mAbs were shown to bind to the guanidine-denatured allergen. The concentration of C5 or D4 that gave the half of maximum absorbance on this sandwich ELISA was estimated to be 1.6 × 10⁻¹⁰ and 2 × 10⁻¹⁰ M (Fig. 1). However, the allergen that was denatured with SDS showed less affinity to C5 than the guanidine-denatured allergen. To examine whether the two mAbs bind to the same epitope on the allergen, the allergen was digested with lysyl endopeptidase. The proteolytic products were immunoblotted with the mAbs (Fig. 2). D4 was shown to bind with the 24.5-, 21.0-, and 19.7-kDa peptides besides the original allergen. C5 showed no clear binding profiles to all the proteolytic products. These findings suggested that the
Fig. 1. Binding of C5 (A) and D4 (B) to the allergen, which was dialyzed against 50 mM phosphate buffer containing 6 M guanidine. After the removal of guanidine from the dialysate by extensive dialysis against PBS, the dialysate was subjected to experiments for the binding of the mAbs. The condition was described in the text.

Fig. 2. Immunoblots of the proteolytic products obtained from Gly m Bd 28K. After SDS-PAGE, the intact allergen and the proteolytic products were electrophoretically transferred onto nitrocellulose membranes. The protein and the peptides on the membrane were immunoblotted with D4 or C5 (A: stained with Amido Black 10B, B: immunoblotted with D4, C: immunoblotted with C5). M, standard proteins; 1, the intact allergen; 2, the products of the allergen digested with lysyl endopeptidase. The standard proteins used were as follows: phosphorylase b (94 kDa), bovine serum albumin (67 kDa), ovalbumin (45 kDa), carbonic anhydrase (30 kDa), soybean trypsin inhibitor (20.1 kDa), α-lactoglobulin (14.4 kDa).

two mAbs recognize the distinct epitopes on the allergen and demonstrated that they can be used in a sandwich ELISA system.
**Development of sandwich ELISA for Gly m Bd 28K**

We examined in detail the conditions suitable for a sandwich ELISA of Gly m Bd 28K. Finally, the sandwich ELISA system described in the materials and methods was established. As Fig. 3 shows, 0.2 to 20 ng of the allergen could be favorably determined by this method.
Analyses of Gly m Bd 28K in soybean products

Before the analyses of the allergen in soybean products by the sandwich ELISA, the extraction procedures for proteins from soybean products were investigated. As described in the previous paper (8), Tris-HCl buffer containing SDS is effective for the extraction of proteins in the soybean products. Because CS used in the ELISA system had less affinity for the allergen denatured in the presence of SDS, the buffer system of 50mM potassium phosphate buffer (pH 8.0) containing 6M guanidine and 10mM 2-mercaptoethanol was employed. As shown in Table 1, it was demonstrated that this buffer system was effective for a quantitive extraction of the proteins in the soybean products, except for meatballs. The extract was subjected to the chromatography on a Sephacryl S-200 column to remove a bulk of proteins other than allergen. The recovery of the allergen from the gel filtration was estimated to be 92.7% by the addition of the isolated Gly m Bd 28K as an internal standard.

Using the above-mentioned sandwich ELISA, we determined the amount of Gly m Bd 28K in various soybean products (Table 2). The allergen was shown to occur at high concentrations in SPI, kori-dofu, and yuba, as found in soybean seeds. The allergen contents of soybean seeds, tofu (momen), kori-dofu, and yuba were shown to be almost the same values from one another based on nitrogen contents. These results suggest that most of the allergen in the original soybean seeds remains without its destruction or reduction during processing. Soy milk and abura-age also contained significant amounts of the allergen. A soy milk sold

Fig. 4. Immunoblots of Gly m Bd 28K in soybean products. A: stained with Coomassie Brilliant Blue R 250. B: immunoblotted with D4. Sample: 1, purified Gly m Bd 28K; 2, soybean seed; 3, soy milk; 4, tofu (momen); 5, kori-dofu; 6, abura-age; 7, yuba; 8, miso; 9, shoyu; 10, natto; 11, meatballs; 12, beef croquettes; 13, fried chicken; 14, fish sausage; 15, hamburger; 16, SPI.
commercially as a drink was shown to contain a relatively low amount of allergen compared with fresh soy milk that had been made in our laboratory. The allergen in the commercial soy milk might be reduced during preparation. The reduction of the allergen in abura-age was considered to be due to denaturation under high temperature during processing. All the above-mentioned products were found to contain three orders less Gly m Bd 28K than Gly m Bd 30K (8). No Gly m Bd 28K could be detected in the fermented soybean products, as shown in the case of Gly m Bd 30K (8–10). Gly m Bd 30K occurs at a significant concentration in meatballs, beef croquettes, and fried chicken, but no Gly m Bd 28K was shown to occur in the foods with SPI as additive in the present study. This suggests that Gly m Bd 28K may tend to be destroyed during the preparation of the products. The other processed foods, fish sausage and hamburger, also contained no Gly m Bd 28K.

To confirm these results obtained with the sandwich ELISA, the allergen in the soybean products was examined by using an immunoblotting technique with D4. Since D4 shows stronger affinity for the guanidine-denatured allergen than C5, D4 was used for the immunoblot analyses. Of the soybean products, the immunoblotting patterns of the allergen in tofu, yuba, abura-age, soy milk, natto, soy sauce, meatballs, fish sausage, and SPI, which had been obtained with C5, had been reported in the previous paper (1). These patterns were quite comparable with those obtained with D4 (Fig. 4). Soybean seed, soy milk, tofu, kori-dofu, abura-age, and yuba gave an intense band corresponding to the allergen, but the allergen in the fermented products could not be detected. Meatballs, beef croquettes, fried chicken, and hamburger were shown to contain no Gly m Bd 28K. Although miso gave an intense band corresponding to a peptide with a molecular mass of 21 kDa, the band was found to be due to a non-specific binding of peroxidase-conjugated anti-mouse IgM. In tofu, many peptides having molecular masses of less than 26 kDa were bound by the antibody, indicating that these bands were obtained by non-specific binding peroxidase-conjugated anti-mouse IgM. The immunoblotting analyses support the results obtained with the sandwich ELISA. These observations and the findings provide useful information to soybean-sensitive patients in the safe selection of soybean products. Furthermore, the sandwich ELISA for m Bd 30K and 28K will be useful tools for the in vitro evaluation of the allergenicity of soybean products.
