(Received October 12, 2000)

Summary We investigated dietary effects of cabbage fermentation extract (CFE) and young barley leaf powder (YBLP) on rat immune functions. Male Sprague-Dawley rats of 4 wk age were fed for 3 wk diets containing these samples at 0.1 or 1% level. After the feeding period, serum IgG level was significantly higher in the rats fed 1% CFE. IgG productivity of spleen lymphocytes was enhanced dose-dependently in both groups of CFE and YBLP. Furthermore, IgG productivity of mesenteric lymph node (MLN) lymphocytes was approximately 2 times higher in the rats fed 1% CFE diet than in the control ones. IgA productivity of MLN lymphocytes tended to increase in both of CFE and YBLP groups. From these results, it was suggested that dietary CFE and YBLP reinforced Ig productivity in both systemic and intestinal immune systems. Moreover, CFE feeding tended to enhance the production of TNF-α by spleen lymphocytes. In spleen phospholipids, the level of arachidonic acid, a substrate for inflammatory lipid mediators, was not affected by CFE or YBLP feeding.

Key Words cabbage fermentation extract, young barley leaf powder, serum immunoglobulin level, immunoglobulin production, rat lymphocytes

Recently, functions in addition to nutritional values and taste have been looked upon as important factors of foodstuffs, and many kinds of functional foods have been developed. For this reason, investigations on physiological effects of functional foods are required.

In previous studies, we have shown that components in plants, for example dietary fibers (1, 2), natural food colorings (3) and vegetable extracts (4), have regulatory effects on Immunoglobulin (Ig) production. These results suggest that foodstuffs derived from vegetables have functions useful for modulation of Ig production. Ig plays an important role in humoral immunity and consists of five classes different in molecular sizes, structures and functions. IgA prevents invasion of exogenous substances from intestinal tract. IgG serves as a main factor for detoxification and clearance of foreign substances in the systemic immune system, and IgM rapidly responds to primary infections. Therefore, we considered that a rise in the level and production of IgA, IgG and IgM was connected with reinforcement of the immune system.

On the other hand, eicosanoids such as prostaglandin and leukotriene also play important roles in the immune system. They are biosynthesized from polyunsaturated fatty acid (PUFA) and closely involved as triggers in inflammatory response and type I allergy (5, 6). We have previously reported that dietary fats and some kind of fatty acids modulate production and release of eicosanoids (7-10). These results suggest that lipid metabolism in the liver and the proportion of PUFA in immune-related tissues and cells are responsible for the modulation of eicosanoid production.

In this study, we investigated dietary effects of cabbage fermentation extract (CFE) and young barley leaf powder (YBLP) on the immune functions in Sprague-Dawley (SD) rats.

MATERIALS AND METHODS

Materials. CFE and YBLP were prepared in Toyo Shinyaku Company, Ltd. (Tokyo, Japan). CFE is a dried powder extracted from fermented chinese cabbage. Washed and milled cabbage leaves were fermented with a lactic acid bacterium, Lactobacillus plantarum. The fermented products were then filtrated and concentrated. After sterilization, the extracts were spray-dried with dextrin. YBLP is a dried powder of young barley leaves. Barley leaves grown to about 30 cm in height were mowed, washed, and dried. The dry leaves were powdered as such without further processing. In the prepa-

Results

Effects of dietary CFE and YBLP on growth of rats

As shown in Table 1, there was no significant difference in weight gain and food efficiency between the CFE group and the control. In the YBLP group, weight gain was suppressed dose-dependently, whereas food intake was not different from that in the control. Consequently, food efficiency was significantly decreased by YBLP feeding. The weights of white adipose tissue, kidney, liver, lung, spleen and heart were not affected by CFE or YBLP feeding (data not shown).

Effects of dietary CFE and YBLP on serum Ig levels and Ig productivity of rat lymphocytes

As shown in Table 2, CFE significantly affected serum levels of Ig except IgA. Serum IgC level in CFE-fed rats was significantly higher than that in the control. On the contrary, CFE feeding caused a decrease in serum IgM level. YBLP did not significantly affect any serum Ig.

Table 3 shows the Ig productivities of spleen and MLN lymphocytes in the rats fed CFE and YBLP diets. The IgA productivity was not affected, whereas the IgG productivity of spleen lymphocytes was significantly enhanced by CFE feeding. The IgM productivity of spleen lymphocytes in the rats fed CFE was significantly lower than in the control. YBLP feeding tended to enhance the IgG production by spleen lymphocytes in a dose-dependent manner. The IgA and IgM productivities of spleen lymphocytes were not affected by YBLP feeding. On the other hand, CFE feeding at a 10% level significantly increased the IgG productivity of MLN lymphocytes. The IgA productivity tended to increase in MLN lymphocytes from the rats fed CFE and YBLP diets.

Effects of dietary CFE and YBLP on production of TNF-α by rat spleen lymphocytes

As shown in Fig. 1, the TNF-α production by spleen lymphocytes tended to be enhanced in CFE-fed groups. On the other hand, YBLP feeding did not affect the production of TNF-α.

Effects of dietary CFE and YBLP on fatty acid composition of spleen phospholipids

After 3 wk's feeding, we measured fatty acid composition of spleen PC (Table 4). Myristate and palmitate contents were lower in the CFE- or YBLP-fed rats than in the control. CFE or YBLP feeding at a 1% level also affected the contents of some kinds of PUFAs. Arachidonic acid content was increased, and docosahexaenoic acid content was decreased. Dramatic changes of PUFAs contents in spleen PC, however, were not observed. On the other hand, the composition of PUFAs in PE was not affected by either CFE or YBLP feeding (data not shown).

DISCUSSION

In this study, we investigated dietary effects of two functional foods, CFE and YBLP, on immune functions of SD rats.

CFE is a dried powder extracted from cabbage leaves fermented by a sort of lactic acid bacterium. It has been long thought that components in cabbage have anticancer properties (16, 17). In this regard, we showed that CFE feeding tended to enhance the production of TNF-α by spleen lymphocytes. It has been also reported that some kinds of lactic bacteria belonging to the genus *Lactobacillus* and *Streptococcus* enhance the production of such cytokines as TNF-α in mice and human lymphocytes (18). Therefore, not only cabbage-derived components but also bacteria-related ones or metabolites in CFE may modulate the production of TNF-α. However, key components involved in the modulation of TNF-α production have not been identified yet. On the other hand, dietary effects of cabbage products on Ig production remained obscure, but we showed a few years ago that water-soluble components in cabbage stimulated IgA and IgG production of rat MLN lymphocytes in vitro (4). In this study, it was suggested that some components contained in cabbage might stimulate IgA and IgG production of MLN lymphocytes in vivo as well as in vitro. Moreover, CFE feeding increased serum IgG level and IgG productivity of spleen lymphocytes. These results suggest that CFE contributes to the modulation of Ig production in both systemic and intestinal immune systems.
YBLP consists purely of young barley leaves, which are rich in dietary fiber accounting for 52.1% of all nutrients. In the previous study, some water-soluble dietary fibers increased rat serum IgG levels and reinforced IgA productivity of MLN lymphocytes compared to cellulose (1). Similarly, it was reported that indigestible polysaccharides increased IgA level in the small intestine (19). A quite similar tendency was obtained in this study as well. On the other hand, flavonoids predominate in leaves of various cereal crops, and a novel anti-oxidant has been isolated from young green barley leaves (20, 21). We have reported that such antioxidants as \( \alpha \)-tocopherol and tea polyphenols modulate Ig or chemical mediator production both in vitro and in vivo (22-25). Therefore, these factors might play a part in the modulation of Ig production by dietary YBLP, but the mechanism has not been revealed yet. In addition, YBLP might serve to prevent obesity because its feeding caused a decrease in food efficiency.

It is considered that the contents of PUFA in immune-related tissues and cells are an important factor in the modulation of inflammatory response and type I allergy (5-8). We could not observe any effects of CFE or YBLP feeding on fatty acid composition in spleen phospholipids. Therefore, they may have no anti-inflammatory effects. It is necessary to investigate the possibility of deterioration of inflammatory response caused by their feeding.

In conclusion, dietary CFE and YBLP modulate Ig production of rat lymphocytes in both systemic and intestinal immune systems. CFE feeding tends to enhance the production of TNF-\( \alpha \) by spleen lymphocytes. It thus seems likely that CFE and YBLP serve as supplemental foodstuffs effective for immune stimulation. It remains to be further investigated whether the modulation of immune parameters by feeding CFE or YBLP is effective in treatment of infectious disease, allergy, cancer and so on.
