Dissymmetric Gemini Surfactants Generated by Disulfide Exchange in Mixed Micelles

Tsuyoshi Asakawa*, Hirotaka Tango, Tadahiro Ozawa and Akio Ohta

Abstract: We found the generation of dissymmetric gemini surfactants from symmetric ones in aqueous micelle solutions of gemini surfactants with a spacer containing disulfide linkage. The equilibrium was attained during 5 h incubation at 25°C with 1:2 ratio of symmetric to dissymmetric ones when the total concentrations were sufficiently high compared with monomer concentrations. The generation of dissymmetric form is attributed to the disulfide exchange between the spacer chains, which occurs in the mixed micelles of gemini surfactants with different hydrocarbon chains. The pseudo-phase separation model for micellization was successfully used to predict not only the cmc of binary and ternary mixtures composed of symmetric and dissymmetric gemini surfactants but also the monomer concentrations after the equilibrium. Reversibility of the disulfide exchange was ascertained by the generation of symmetric gemini surfactants from dissymmetric ones.

Key words: dissymmetric gemini surfactant, disulfide linkage, disulfide exchange, mixed micelle, HPLC analysis

1 INTRODUCTION

Gemini surfactants usually consist of two hydrophobic chains with the same chain lengths1. The symmetrical gemini surfactants have been investigated well owing to the unique properties different from those of conventional single-chain surfactants2). Recently, some properties of dissymmetric gemini surfactants have been investigated, and it has been clarified that the disymmetry influences on the micellization process3-5). The effects on the micellization increased as the degree of dissymmetry increased. With the increase in the degree of dissymmetry, the critical micelle concentration (cmc) decreases linearly, the micelle aggregation number increases slightly, the micelle ionization degree decreases slightly, and so on. Wang et al. suggested that the intermolecular and intramolecular interactions between the hydrophobic alkyl chains exist for the symmetric gemini surfactants, while the intramolecular interaction weakens as the degree of dissymmetry increases6). Thus, the hydrophobic interaction of dissymmetric gemini surfactants must be different from that of symmetric ones.

Disulfide bonds are well known to undergo thiol–disulfide exchange reaction7). Regen et al. developed the so-called “nearest–neighbor recognition” method using disulfide linked phospholipids, homodimers A–A and B–B7,8). They indicated that the equilibrium constant \( K = \frac{[A-B]^2}{[A-A][B-B]} = 4\) when A and B mix ideally. The homodimer (A–A) to heterodimer (A–B) ratio of 1:2 is attained due to the disulfide exchange if dimers are randomly distributed and have no thermodynamic preference. In other words, if an equimolar of (A–A) and (B–B) were present, the mole ratio of (A–A) to (A–B) would be 2:1, and the equilibrium constant would be equal to 4. We should note that the measurements were carried out by promoting thiolate–disulfide interchange reactions with the addition of dithiothreitol. The exchange reaction between disulfide bonds has been scarcely reported because of the stability of the disulfide bond. Recently, Leclaire et al. reported the simultaneous exchange between disulfide bonds in aerated aqueous solutions9). HPLC analysis demonstrated that the equilibrium of disulfide exchange was reached in 36 h.

We first attempted to clarify the mixing effects of gemini surfactants in aqueous solution using the surfactants containing a disulfide bond at the center of a spacer chain between the ammonium headgroups. In this work, we found a peculiar behavior in the measurements of the cmc for the mixed surfactant systems. If the disulfide exchange between gemini surfactants occurs, one type of dissymmetric gemini surfactant can be generated. This may be an origin of the
peculiar behavior of the cmc observed for the mixed gemini surfactants. It should be noted that the disulfide exchange was performed without the addition of dithiothreitol in aerated aqueous solutions at 25 °C.

In the present work, the conditions of HPLC analysis were optimized for the separation and determination of symmetric and dissymmetric geminis. Then, the time course of the concentration change for each surfactant was examined up to the equilibrium. The effects of mixing ratios and concentrations of surfactants were investigated in the mixtures of geminis containing different alkyl chain lengths. The equilibrium constant was estimated by the micellized surfactant concentrations, which were calculated based on the pseudo–phase separation model for micellization. The reversible conversion between symmetric and dissymmetric gemini surfactants was also checked by the HPLC analysis.

2 EXPERIMENTAL

2.1 Materials

Bis[N–alkyl–N,N–dimethyl–N–(2–mercaptopethyl) ammonium bromide] disulfide, C₃H₆N+(CH₃)₂CH₂CH₂SS CH₂CH₂N+(CH₃)₂C₃H₆+2Br⁻(C₃SSC₃) was prepared by similar procedures to those reported previously as briefly mentioned below. Bis[2–(N,N–dimethylaminoethyl)] disulfide dihydrochloride (Wako Pure Chemical Industries, Ltd.) was mixed with twice moles of sodium ethoxide in ethanol. After the removal of precipitated NaCl, the solution was stirred with 2.2 times moles of 1–bromoalkane at 40°C for 2 days. After the evaporation of ethanol, the products were washed with acetone and were purified by repeated recrystallization from acetone–ethanol mixtures.

2.2 Measurements

The gemini surfactants were analyzed by TSKgel ODS–100V (TOSOH Co.) column using methanol / 30 mM sodium 1–octanesulfonate (85:15) mixture as an eluting solution. The elution of surfactant was monitored by CM–8010 (TOSOH Co.) electrical conductivity detector. Aqueous solutions of C₉SSC₉ and C₁₀SSC₁₀ were prepared in volumetric flask separately. The same volumes of C₉SSC₉ and C₁₀SSC₁₀ aqueous solution at given concentrations were mixed in test tubes using digital pipette. They were incubated at 25°C without stirring. Generated dissymmetric gemini surfactant was isolated by the same HPLC system using 85:15 methanol / 0.4M NaCl aqueous solution as an eluting solution. The portions of C₉SSC₉ were collected in test tubes. They were concentrated by evaporation of methanol under reduced pressure. The conductivity measurements of aqueous surfactant solutions were carried out at 25°C using a conductivity meter, Model DS–12 (HORIBA).

3 RESULTS AND DISCUSSION

3.1 Generation of dissymmetric gemini surfactant from symmetric ones

We have found that the cmc of equimolar C₁₀SSC₁₀–C₁₂SSC₁₂ mixture subjected to incubation was larger than that of fresh–prepared sample. This fact suggested a possibility that a certain chemical reaction took place in the solution during the incubation. In order to check this possibility, HPLC experiments were carried out. Figure 1 shows that a new peak appears in HPLC analysis of C₁₀SSC₁₀–C₁₂SSC₁₂ aqueous solutions during the incubation. The elution peaks of C₁₀SSC₁₀ and C₁₂SSC₁₂ were observed at 4.5 and 9.5 min, respectively, while the new peak was detected at 6.1 min. The new peak corresponds to dissymmetric gemini surfactant, C₁₀SSC₁₂, generated by disulfide exchange between C₁₀SSC₁₀ and C₁₂SSC₁₂. The small peak of C₁₀SSC₁₀ was observed even after 5 min incubation.

3.2 Effect of concentration on generation of Dissymmetric gemini surfactant

Figure 2 shows the time course of the surfactant concentration change observed for 25 mM C₁₀SSC₁₀–25 mM C₁₂SSC₁₂ aqueous solution. The concentrations of both C₁₀SSC₁₀ and C₁₂SSC₁₂ decrease with the incubation time, while that of C₁₀SSC₁₂ increases significantly. The concentration of C₁₀SSC₁₀ always coincided with that of C₁₂SSC₁₂ within experimental error. The surfactant concentrations become almost constant after 120 min incubation. The concentration ratio of C₁₀SSC₁₀ to C₁₀SSC₁₂ was almost 1:2 at equilibrium.

\[
C_{10}SSC_{10} + C_{12}SSC_{12} \rightarrow 2C_{10}SSC_{12}
\]  
(1)

Similar experiments to C₁₀SSC₁₀–C₁₂SSC₁₂ system were also performed for C₁₀SSC₁₀–C₁₄SSC₁₄ and C₁₂SSC₁₂–
Dissymmetric Geminis by Disulfide Exchange in Micelles

Fig. 3 Concentrations of Generated Dissymmetric Gemini Surfactants at Equilibrium. Total surfactant concentration is 10 mM. (●) C_{10}SSC_{12}, (▲) C_{10}SSC_{14}, (■) C_{12}SSC_{14}

C_{14}SSC_{14} systems in the concentration range up to the solubility limit of C_{14}SSC_{14}. Figure 3 shows the equilibrium concentrations of dissymmetric C_{m}SSC_{n} for C_{m}SSC_{m} – C_{n}SSC_{n} system as a function of mole fraction of C_{n}SSC_{n} at fixed total surfactant concentrations of 10 mM. The concentrations of generated dissymmetric C_{m}SSC_{n} have a maximum at the equimolar mixtures. The maximum concentration of dissymmetric C_{m}SSC_{n} is 5.12 mM for C_{12}SSC_{14}, whereas those for C_{10}SSC_{12} and C_{12}SSC_{14} are smaller than 5 mM. Thus, concentration ratio 1:2 for symmetric C_{m}SSC_{m} to dissymmetric C_{m}SSC_{n} is attained only for C_{12}SSC_{12} – C_{14}SSC_{14} system when total concentration is fixed at 10 mM. The generation of dissymmetric C_{m}SSC_{n} may be influenced by the cmc of surfactant, that is to say, the monomer concentrations in equilibrium with mixed micelles. Thus, the effect of surfactant concentration on the generation of dissymmetric C_{m}SSC_{n} was examined.

Figure 4 shows the dependence of the generation of dissymmetric C_{m}SSC_{n} on total surfactant concentration of equimolar mixture of symmetric gemini surfactants. The total concentrations for C_{10}SSC_{10} – C_{14}SSC_{14} and C_{12}SSC_{12} – C_{14}SSC_{14} systems were examined up to the solubility limit of C_{14}SSC_{14}. The concentration of dissymmetric C_{m}SSC_{n} increases with the increase of the total surfactant concentration. The ratio, [C_{m}SSC_{n}]/[C_{n}SSC_{n}], increases up to almost 2 for C_{12}SSC_{12} – C_{14}SSC_{14} and C_{10}SSC_{10} – C_{12}SSC_{12} systems at high concentrations, whereas the ratio for C_{10}SSC_{10} – C_{14}SSC_{14} system is rather low.

Then we tried the disulfide exchange between C_{2}SSC_{2} and C_{12}SSC_{12} in aqueous solutions. However, C_{12}SSC_{2} was not generated during the incubation even for several days. These results suggest that the disulfide exchange can occur in mixed micelles as illustrated in Scheme 1. If this is the case, the concentration of generated dissymmetric C_{m}SSC_{n} must be dependent on the micellized concentrations of the gemini.
surfactants. Thus, in order to interpret the dependence of $C_nSSC_n$ generation on the total concentration, the composition of the mixture, and the species of symmetric gemini surfactants, we should take into account the monomer concentrations, or in other words, the cmc values of gemini surfactants, we should take into account the composition of the mixture, and the species of symmetric gemini surfactants. The cmc values of monomer concentrations, or in other words, the cmc values of symmetric gemini surfactants, should be estimated by equimolar $C_{10SSC_{10}} – C_{12SSC_{12}}$ mixture is much larger than that of monomeric $C_{14SSC_{14}}$, the micelle composition is $C_{14SSC_{14}}$–rich even for equimolar $C_{10SSC_{10}} – C_{12SSC_{12}}$ system. Therefore, the concentration of generated $C_{10SSC_{10}}$ becomes lower than those of other systems.

Figure 4 demonstrates that the concentration of generated dissymmetric $C_nSSC_n$ increases and approaches a constant value with the increase of the total surfactant concentration. This is because the micelle composition becomes close to the total composition at high concentration. The similar behavior can be anticipated by the addition of salts, since the coexistence of inorganic salts reduces the cmc. Table 1 shows the effect of NaCl addition on the concentrations of gemini surfactants at equilibrium. The concentration of generated symmetric $C_{10SSC_{12}}$ is increased by the addition of 0.4 M NaCl. The concentration ratios of symmetric $C_{10SSC_{12}}$ to dissymmetric $C_{14SSC_{14}}$ become to be close to 1:2 when the concentration of supporting electrolyte increases. This is because the micelle composition is close to the total composition of the mixed surfactant solution due to the reduced cmc caused by the addition of NaCl. The apparent equilibrium constant, $K_{app}$, can be defined as follows using equilibrium concentrations of the three surfactant species in the solution,

$$K_{app} = \frac{[C_{10SSC_{12}}]^2}{[C_{10SSC_{10}}][C_{12SSC_{12}}]} \quad (2)$$

At first glance, the value of $K_{app} = 2.04$ seems to indicate that the generation of dissymmetric gemini surfactant is in disfavor of $C_{10SSC_{10}} - C_{12SSC_{12}}$ system. However, the value of $K_{app}$ becomes about 4 with the increase of total surfactant concentration probably because the monomeric concentrations can be negligible compared with the micellized concentrations.

It is reasonable to assume that the equilibrium of disulfide exchange between gemini surfactants is attained in micelle phase, as mentioned above. Then, the equilibrium constant, $K_{eq}$, should be expressed in terms of equilibrium concentrations of each surfactant species in micelles.

$$K_M = \frac{[C_{10SSC_{12}}]_M^2}{[C_{10SSC_{10}}]_M [C_{12SSC_{12}}]_M} \quad (3)$$

At equilibrium, the aqueous solution contains three components of surfactants. In order to estimate their equilibrium concentrations in micelles from the total concentration, it is necessary to know the monomeric concentrations of each component. We can calculate the monomeric concentrations on the basis of the pseudo–phase separation model for micellization using a regular solution approximation. According to this model, the total monomeric concentration of ternary system is given by,

$$C_{im} = \sum_{i=1}^{3} C_i = C_m \quad (4)$$

where $C_m$ is cmc of mixed surfactant system, $C_i$ is the cmc of surfactant $i$ in single system, $K_g$ is the micelle counterion binding parameter, $x_i$ is the mole fraction of surfactant $i$ in the mixed micelle, and $f_i$ is the activity coefficient of surfactant $i$ in the micelle. The $K_g$ value can be estimated by assuming the additivity of $K_g$, where the subscript $i$ refers to surfactant $i$. The monomeric concentration of surfactant $i$ in the mixture, $C_{im}$, can be calculated by the following relations:

$$C_{im} = C_i \cdot K_g \cdot x_i f_i \quad \frac{C_{im}}{C_m} = \frac{C_i}{K_g} \quad (5)$$

The mole fraction of surfactant $i$ in the mixed micelle is given by the relationship of mass balance.

$$x_i = \frac{\alpha_i C_i - C_{im}}{C_t} \quad (6)$$

where $\alpha_i$ is the mole fraction of surfactant $i$ in the overall ternary mixture and $C_t$ is the total surfactant

J. Oleo Sci. 59, (2) 95-100 (2010)
concentration. Thus, we can calculate \( C_{\text{in}} \) being in equilibrium with mixed micelles at \( C_t \) using equations 4 - 6. However, we cannot determine the cmc of the dissymmetric gemini surfactant in single system because the symmetric gemini surfactants are soon generated by the disulfide exchange in the micellar aqueous solutions. Therefore, we estimated the cmc of the dissymmetric gemini surfactant by using the linear relationship between log cmc and total carbon number \( (C_n) \) of two hydrophobic chains. The cmc of \( C_{10}\text{SSC}_{12} \) was estimated to be 2.23 mM from the experimental relation of log cmc = 2.10 – 0.216 \( C_n \) for \( C_{10}\text{SSC}_{10} \), \( C_{12}\text{SSC}_{12} \), and \( C_{14}\text{SSC}_{14} \) systems. For \( C_{10}\text{SSC}_{10} \)-\( C_{10}\text{SSC}_{12} \)-\( C_{12}\text{SSC}_{12} \) ternary system which is shown in the first row of Table 1, the pseudo–phase separation model presuming ideal mixing i.e., \( f_1 = 1 \), predicts that the monomer concentrations of \( C_{10}\text{SSC}_{10} \), \( C_{10}\text{SSC}_{12} \), and \( C_{12}\text{SSC}_{12} \) are 1.84, 0.83 and 0.14 mM, respectively. Thus, the equilibrium constant for disulfide exchange in the micelle phase can be calculated as \( K_M = (4.33–0.83)^2/(2.83–1.84) (3.24–0.14) = 3.99 \) by using Eq. 3 and the concentration data listed in Table 1. The \( K_M \) value is in excellent agreement with the expected \( K_M = 4 \).

The cmc values of the present mixed surfactant systems were determined from conductivity measurements. The cmc of binary system was obtained by using fresh–prepared aqueous solutions of equimolar symmetric gemini surfactants. On the other hand, the cmc of ternary system was obtained by rapid measurements after the dilution of equilibrated equimolar mixture of symmetric gemini surfactants with total concentration of 100 mM. The cmc of equimolar \( C_{10}\text{SSC}_{10} – C_{12}\text{SSC}_{12} \) was 1.29 mM in accord with calculated cmc (1.30 mM) presuming ideal mixing. The cmc of \( C_{10}\text{SSC}_{10} – C_{12}\text{SSC}_{12} \) (1:2.1) was 1.54 mM, which was also in fair agreement with the calculated cmc (1.59 mM). The calculation demonstrated that the cmc value of ternary system was rather larger than that of binary system before disulfide exchange because the concentration of lower cmc component \( C_{10}\text{SSC}_{12} \) decreased, even though the concentration of higher cmc component \( C_{10}\text{SSC}_{10} \) decreased simultaneously.

3.3 Generation of symmetric gemini surfactants

In closing, we should like to confirm the reverse reaction in the chemical equilibrium (1). The dissymmetric gemini surfactant \( C_{10}\text{SSC}_{12} \) was collected by HPLC elution using methanol / 0.4M NaCl aqueous solution (85:15) without sodium 1–octanesulfonate because the anionic component can influence the micellization behavior. Figure 5 shows the HPLC analysis of \( C_{10}\text{SSC}_{12} \) aqueous solution. The elution peak of \( C_{10}\text{SSC}_{12} \) was observed, while the small elution peaks of \( C_{10}\text{SSC}_{10} \) and \( C_{12}\text{SSC}_{12} \) were also detected even for the case of 5 min incubation after isolation. After 24 h, the dissymmetric \( C_{10}\text{SSC}_{12} \) decreased, while the symmetric \( C_{10}\text{SSC}_{10} \) and \( C_{12}\text{SSC}_{12} \) increased as expected.

4 CONCLUSION

We found the generation of dissymmetric gemini surfactants from symmetric ones with 1:2 ratio of symmetric to dissymmetric ones when the total concentration was sufficiently high. The concentration of generated dissymmetric \( C_m\text{SSC}_n \) depended on the micellized concentrations of symmetric gemini surfactants, suggesting the occurrence of disulfide exchange in the mixed micelles. The pseudo–phase separation model for micellization predicted the cmc of binary and ternary mixed surfactant systems composed of symmetric and dissymmetric geminis, which was in accordance with experimentally determined cmc. The model also predicted the monomeric and micellized concentrations, resulting in the equilibrium constant for disulfide exchange in the micelle phase, i.e., \( K_M = 4 \). These results indicated the disulfide exchange can occur in the micelle phase as illustrated in Scheme 1.
