Photodegradation of Mepronil

Takashi YUMITA* and Izuru YAMAMOTO

*Department of Agricultural Chemistry, Tokyo University of Agriculture,
Setagaya-ku, Tokyo 156, Japan*

(Received October 17, 1981)

Mepronil remaining after 80 days exposure to sunlight on the silica gel chromatoplate was 34.1 and 62.2% depending on the season (Sept. to Dec. and Nov. to Jan., respectively). The half-life is estimated as 36 days during Sept. to Dec. which was shortened to half when a photosensitizer, xanthone, was mixed with it. The degradation in water when irradiated with ultraviolet light was only 32.0% after 80 hr at 30°C. Twelve photoproducts were identified as 3'-(1-hydroxymethylethoxy)-2-methylbenzanilide; 3'-isopropoxy-2-hydroxy-methylbenzanilide; 3'-isopropoxy-4'-hydroxy-2-methylbenzanilide; 3'-hydroxy-2-methylbenzanilide; 1-hydroxy-3-oxo-2-(3'-isopropoxyphenyl)isoindoline; 3'-(1-carboxyethoxy)-2-methylbenzanilide; 3',4'-dihydroxy-2-methylbenzanilide; 2-methylbenzamide; 2-methylbenzoic acid; 2-hydroxymethylbenzoic acid; phthalide; and 2-carboxybenzaldehyde. The results indicate that initially hydroxylation of mepronil occurs on the four positions, followed by further oxidation, hydrolysis, cyclization or cleavage.

INTRODUCTION

Mepronil (3'-isopropoxy-2-methylbenzanilide) or Basitac®, the name registered by Kumiai Chemical Industry Co., is a new fungicide which has strong fungicidal activity against rice sheath blight fungus in particular. In previous papers the degradation of mepronil in soils¹⁾ and plants²⁾ was reported. In this report results of an investigation on the degradation of ¹⁴C-mepronil exposed to sunlight and ultraviolet rays are given as a part of the evaluation of the ecotoxicological safety of mepronil.

MATERIALS AND METHODS

1. Chemicals

Two ¹⁴C-mepronil preparations, [aniline-¹⁴C]mepronil (specific activity, 2.72 mCi/mmol) and [carbonyl-¹⁴C]mepronil (specific activity, 3.45 mCi/mmol) were used in these studies.

These were synthesized by the Tokyo College of Pharmacy (Hachioji, Tokyo), and their radiochemical purities were shown to be more than 99%. Table 1 shows the structures and *R_f* values on thin-layer chromatography (*tlc*) of mepronil-related compounds. These authentic compounds were purchased or prepared by the Chemical Research Institute, Kumiai Chemical Co., Ltd. (100 Shibukawa, Shimizu, Shizuoka 424, Japan). The properties of I, III, IV, VII, VIII, IX, XIII and XIV have been described in a previous paper.¹⁾ Properties of other synthesized compounds are as follows:

Compound II, mp 73°C; IRν cm⁻¹ (KBr): 1,500 (CO), 1,590, 1,500 (phenyl). Compound V, mp 111–113°C; bp 263°C. Compound VI, mp 161–162°C; NMR(CD₃COCD₃)δ: 1.34 (6H, d *J*=6 Hz), 4.65 (1H, m *J*=6 Hz), 6.95–7.10 (3H, m arom.), 7.66 (1H, s), 7.90 (4H, s arom.); IRν cm⁻¹ (KBr): 3,430 (OH), 1,700 (CO), 1,610, 1,510 (phenyl). Compound X, mp 141–142°C; NMR(CD₃COCD₃)δ: 2.47 (3H, s), 6.17–8.33 (6H, m arom. & NH₂); IRν cm⁻¹ (KBr): 3,380, 1,190 (NH₂), 1,610, 1,490 (phenyl), 1,645 (CO). Compound XI, mp 92–93°C; IRν cm⁻¹ (KBr):

2. Exposure of ¹⁴C-Mepronil to Sunlight on Silica Gel Chromatoplate

A mixture of [aniline-U-¹⁴C]mepronil (20.9 μ g, 0.21 μ Ci) and unlabeled mepronil (80 μ g) was dissolved in 0.5 ml of methanol. [Carbonyl-¹⁴C] mepronil (31.8 μ g, 0.41 μ Ci) was dissolved in 0.5 ml of methanol. When needed, [aniline-U-¹⁴C] mepronil and [carbonyl-¹⁴C]mepronil were mixed with photosensitizer xanthone 3.6 and 2.3 times respectively in 0.5 ml of methanol. Each sample was spotted on a corner of a two-dimensional *tlc* plate; the plate was then covered with a thin film of polychlorovinylidene and exposed to sunlight for a prescribed period of time.

For preparing a larger amount of photo-products, an acetone solution of unlabeled mepronil (15 mg) and xanthone (15 mg) was spotted on the plates and, after exposure to sunlight for 20 days, each photoproduct was separated by *tlc*.

3. Irradiation with Ultraviolet Rays in Water

In a 300 ml irradiation vessel, 1.03 ppm of

mepronil ([aniline-U-¹⁴C] mepronil, 0.16 mg, 1.62 μ Ci and unlabeled mepronil, 0.15 mg) were dissolved in 300 ml of distilled water and irradiated by a high-pressure mercury lamp with a maximum intensity of 365 nm (Riko Kagaku Sangyo Model UVL-100-300P, 100 W) at 30°C for a prescribed time. [Carbonyl-¹⁴C]mepronil (0.22 mg, 2.83 μ Ci) mixed with unlabeled mepronil (0.15 mg) was dissolved in 300 ml of distilled water (1.23 ppm) and irradiated at 20°C; 20 or 30 ml of the solution was extracted three times using 50 ml of dichloromethane each time. The dichloromethane extract was concentrated and a portion of it was spotted on a chromatoplate.

For preparing a larger amount of the photo-products, an aqueous solution (1.5 ppm) of unlabeled mepronil (0.5 mg) was irradiated at 30°C for 7 days. Photoproducts after extraction with dichloromethane were separated by *tlc*.

4. Thin-layer Chromatography and Autoradiography

A silica gel 60 chromatoplate (without fluorescent indicator, precoated, 20×20 cm, 0.25 mm thickness, E. Merck) was used for exposure to sunlight, and silica gel 60F₂₅₄ (with fluorescent indicator, precoated, 20×20 cm, 0.25 mm thickness, E. Merck) was used for

purification and identification. Several solvent systems were examined; three of these are shown in Table 1. The plates were developed in two-dimensional ways, first with *n*-hexane/dioxane (2/1) and secondly with benzene/methanol (19/1). After having been developed and dried, the chromatoplates were contacted with X-ray film [Konishiroku Photo Ind. X-ray film, JX (10×12) 25.4×30.5 cm] for 7 days for preparation of the autoradiogram. Spots of unlabeled compounds were detected under ultraviolet lamp (254 nm).

5. Radioassay

One ml aliquot of the irradiated solution was dissolved with 12 ml of hydrophilic scintillator (DPO 4.0 g, POPOP 0.4 g, naphthalene 100 g, toluene 150 ml, ethyl cellosolve 100 ml, and dioxane 750 ml, to make 1,000 ml) and radioassayed using a liquid scintillation spectrometer (Aloka, Model LSC-502). The photoproducts were scraped off their chromatoplates with the silica gel and radioassayed as described above.

6. Identification of Degradation Products

The following methods were utilized for identification: The ^{14}C -photoproducts were compared with reference compounds by cochromatography; ^{14}C -photoproducts were methylated with diazomethane or reduced with sodium borohydride and then compared with the methylated or reduced reference compounds by cochromatography; ^{14}C -photoproducts were hydrolyzed by refluxing with concentrated hydrochloric acid and the products were compared with reference compounds by cochromatography; gas chromatography-mass spectrometry (GC-MS) spectra of the unlabeled photoproducts were analyzed and compared with the spectra of reference compounds. A Shimadzu Model LKB-900 was used for the GC-MS. The operating conditions were as follows: column length, 2 m; column packing, OV-1 1.5%/Shimalite W; flow rate of helium, 20 ml/min; column temperature, 260°C; injection temperature, 280°C; ionizing energy, 20 eV and 75 eV.

RESULTS AND DISCUSSION

1. Photoproducts from [Aniline- U - ^{14}C] and [Carbonyl- ^{14}C] Mepronil

The photoproducts obtained by exposure to sunlight on silica gel chromatoplates and by irradiation with ultraviolet rays in water are referred to by LS- and LU-numbers, respectively. In Table 2 all products are indicated by an L-number, for example, LS-1 and LU-1 are L-1. With sunlight, twenty to thirty spots appeared on the autoradiogram from two ^{14}C -mepronil preparations after exposure to sunlight for 20 days, among which rather distinct spots (LS-1~LS-14) are shown in Fig. 1.

Over ten spots were common in photoproducts from [aniline- U - ^{14}C] and [carbonyl- ^{14}C] mepronil; this would indicate that they retain the anilide-linkage. On the other hand, several photoproducts were detected from [carbonyl- ^{14}C]mepronil alone which seem to be derived from only the *o*-toluic acid moiety. Photoproducts from [aniline- U - ^{14}C]mepronil alone were not detected. LS-14 is a mixture of high-polar substances remaining at the *t*_{lc} origin, from which several substances (L-14a~d) were obtained by methylation with diazomethane. The identification or characterization of the photoproducts are summarized in Table 2. Two unknowns were characterized by GC-MS, though not identified: LS-3 (UK-1), *m/z* 297 (M^+ base peak), 255, 240, 224, and LS-4 (UK-2), *m/z* 267 (M^+), 225 (base peak).

Figure 2 shows the autoradiograms from two ^{14}C -mepronil preparations irradiated with ultraviolet rays in water for 80 hours. Three spots (LU-1, LU-6 and LU-10) were found to be common to both ^{14}C -mepronils, indicating that these products retain the anilide-linkage. On the other hand, three spots (LU-2, LU-5 and LU-12) were detected from [carbonyl- ^{14}C]mepronil alone, indicating that these were cleaved photoproducts with only an *o*-toluic acid-derived moiety. Photoproducts originating from [aniline- U - ^{14}C]mepronil alone were not detected. Results of the identification are also shown in Table 2.

2. Fates of Mepronil and its Photoproducts

In Fig. 3 results are shown of the degrada-

tion with sunlight for 80 days (between Sept. 22, 1977 and Dec. 10, 1977) using [aniline-U-¹⁴C] mepronil. The remaining mepronil during the period decreased from 84.8% (5 days after application) to 34.1% (80 days), 35.2% of the radioactivity was lost from the chromatoplates after 80 days. Radioactivity at the *llc*

origin (LS-14) increased gradually to 21.5% after 80 days. The amounts of other identified or unknown products were not significant. With xanthone as a photosensitizer, degradation of mepronil was accelerated at the rate of 1.5–2 times. Results of degradation with sunlight for 80 days (between Nov. 16, 1977

and Jan. 30, 1978) using [carbonyl- ^{14}C] mepronil are also shown in Fig. 3. The amount of remaining mepronil must be the same, though differently labeled in position, if the irradiation conditions are the same. However, the remaining mepronil during the period decreased from 96.1% (5 days after application) to 62.2% (80 days). Such difference between aniline- and carbonyl-labeled mepronils would be due to milder conditions applied on the carbonyl-labeled mepronil. Loss during exposure (5.9%) and the radioactivity at the origin (9.4%) were also lower. However, the greater loss of radioactivity from [aniline-U-

^{14}C]mepronil seemed mostly attributable to the loss of aniline-derived products when they formed because such products were not observed, whereas the corresponding acid-derived products were observed. Xanthone also increased photodegradation of [carbonyl- ^{14}C]mepronil.

From the plotted curve, the half-life of mepronil during exposure to sunlight is estimated as 36 days, (Sept.-Dec.). When mixed with xanthone, the half-life was shortened to 16.5 days. During exposure to sunlight during Nov.-Jan. a half-life was not estimated but with xanthone it was 48 days.

○: LU-1 (mepronil), ▲: LU-2, ■: LU-5, ●: LU-6, △: Others, □: Unextractable (H_2O).

Fig. 5 Proposed photodegradation pathways for mepronil.

Degradation in water with ultraviolet rays was slow, as shown in Fig. 4. As noted by the difference of remaining mepronil for aniline- and carbonyl-labeled mepronil (68.0% and 81.1% respectively, after 80 hours) the temperature effect has been significant. Formation of LU-6 was remarkable. The radioactivity remained in the aqueous layer after

dichloromethane extraction (unextractable) increased slightly during irradiation, but no organic-soluble products were obtained by methylation.

No half-life of mepronil in water by irradiation with ultraviolet rays was estimated. In brief, mepronil is rather photostable under both conditions tested.

3. Proposed Photodegradation Pathways for Mepronil

The interrelationship among the identified photoproducts is illustrated in Fig. 5. Though mepronil is rather stable, hydroxylation occurs at four positions. The product hydroxylated at methyl group on the acid moiety (L-9) is further converted to 1-hydroxy-3-oxo-2-(3'-isopropoxyphenyl)isoindoline (L-6) by oxidation-cyclization. This product seems to be a terminal product as further irradiation under the conditions stated did not change it. The intermediate (not identified) hydroxylated at the center carbon of the isopropoxy group on the aniline moiety is unstable and degraded to 3'-hydroxy-2-methylbenzanilide (L-10). Hydroxylation also occurs at the terminal carbon of the isopropoxy group giving 3'-(1-hydroxymethylethoxy)-2-methylbenzanilide (L-11), which is further oxidized to give 3'-(1-carboxyethoxy)-2-methylbenzanilide (L-14d). Hydroxylation at the para position to the amide of aniline moiety gives 3'-isopropoxy-4'-hydroxy-2-methylbenzanilide (L-7). Combinations of these changes give further products, such as 3',4'-dihydroxy-2-methylbenzanilide (L-14c). As shown in Fig. 3, LS-8 (*o*-toluic acid) and LS-12 (*o*-toluamide) appeared from quite early stages during exposure to sunlight and were the major products. The mechanism of the formation of *o*-toluamide is interesting to study. It may require cleavage between amino-nitrogen and phenyl-carbon or amidation of *o*-toluic acid. This work will be reported elsewhere.

ACKNOWLEDGEMENTS

The authors wish to express their thanks to Prof. Shigeru Inaba and other members of the Radioisotope Research Institute, Tokyo University of

Agriculture, for their kind suggestions and also to Prof. Shigeo Baba, Tokyo College of Pharmacy, for the supply of radioactive mepronil. Thanks are also due to Dr. Hironari Sugiyama and Dr. Isao Shimazaki of KI Chemical Research Institute for the supply of non-radioactive chemicals and to Mr. Tadaharu Kitagaki, Mr. Rokuro Shinohara and Mr. Yuzuru Asano of Life Science Research Institute, Kumiai Chemical Co., Ltd., for their valuable advice and GC-MS analyses on this study.
