ABSTRACT—Effect of cholinergic stimulation on the release of digestive enzymes from isolated rat pancreatic acini prepared by collagenase digestion was investigated. The release of enzymes (amylase, chymotrypsinogen, lipase) increased linearly with the time of incubation in the absence of secretagogues. Carbachol, a muscarinic agonist, induced a remarkable increase in the release of these enzymes. This carbachol-stimulated amylase release showed a biphasic curve, and its maximal response was observed at $10^{-5}$ M. The release patterns of chymotrypsinogen and lipase were similar to that of amylase. This carbachol-stimulated amylase release was inhibited by atropine in a dose-dependent manner, with an ED$_{50}$ value of $1.17 \times 10^{-8}$ M. Other cholinergic agonists such as methacholine also stimulated the release of these enzymes, and these increases in the release were inhibited by atropine. Scatchard analysis for $[^3$H]quinuclidinyl benzilate ($[^3$H]QNB) binding to isolated pancreatic acini revealed that the binding site of $[^3$H]QNB was a single component with a $K_d$ value of 0.09 nM and a $B_{max}$ value of 89.3 fmol/mg protein, respectively. The effect of other cholinergic antagonists, pirenzepine and AF-DX 116 (11-[(2-[(diethylamino)methyl]1-piperidinyl)acetyl]-5,11-dihydro-6H-pyrido[2,3-b][1,4]-benzodiazepine-6-one), on pancreatic acini was also investigated. Based on these results, it has been concluded that isolated rat pancreatic acini have muscarinic receptors and are useful for analyzing the mechanism of pancreatic enzyme secretion.

Pancreatic exocrine secretion is regulated by neural and humoral factors (1–3). Recent development in the techniques to isolate pancreatic acinar cells such as enzyme digestion, chelation and mechanical shearing procedures (2, 4, 5) have facilitated the pharmacological analyses of such regulatory mechanisms on pancreatic exocrine secretion. In fact, pancreatic physiological functions including the responsiveness of enzyme secretion to various secretagogues and receptors coupled with pancreatic exocrine function has been clarified (6–9). Amylase secretion has been used as an index for pancreatic exocrine function and for
investigating the regulatory roles of receptor activation on the secretion. In spite of the important physiological roles of pancreatic exocrine glands in the secretion of lipase and chymotrypsinogen as well as amylase, few reports dealing with the mechanisms of in vitro secretion of these enzymes are available (10, 11). Therefore in the present study, we have attempted to examine the functional coupling between muscarinic receptors and enzyme release using isolated rat pancreatic acini prepared by enzyme digestion.

MATERIALS AND METHODS

Materials
Soybean trypsin inhibitor (type I-S) and HEPES (N-2-hydroxy-ethyl-piperadine-N'-2-ethanesulfonic acid) were purchased from Sigma Chemical Co. (St. Louis, U.S.A.). Collagenase (type 4) and minimal Eagle’s medium amino acid supplement were obtained from Worthington Biochemicals (Freehold, U.S.A.) and Gibco (Grand Island, U.S.A.), respectively. Miles Laboratories (Elkhart, U.S.A.) was the source of bovine serum albumin (fraction 5, powder). [3H]Quinuclidinyl benzilate ([3H]QNB, 42.6 Ci/mmol) was purchased from New England Nuclear (Boston, U.S.A.). AF-DX 116 was a kind gift from Boehringer Ingelheim (Elmsford, U.S.A.). Other chemicals used were locally available and of analytical grade.

Preparation of pancreatic acini
Male Wistar rats weighing 200 g to 300 g having free access to laboratory chow and water ad libitum were used for the preparation of pancreatic acini. Pancreatic acini were prepared according to the procedure described previously (6, 12) with a minor modification. Krebs-Henseleit-bicarbonate buffer (KHB) (110 mM NaCl, 32.5 mM NaHCO3, 4.7 mM KCl, 1.13 mM MgCl2, 1 mM Na2HPO4, 2 mM glutamine and 11.1 mM glucose) containing 0.01% trypsin inhibitor and minimal Eagle’s medium amino acid supplement was used as the basic medium. The medium used for preincubation and reaction of enzyme release was HEPES-buffered Ringer solution (HR) containing 127 mM NaCl, 4.7 mM KCl, 1.2 mM CaCl2, 0.56 mM MgCl2, 1 mM Na2HPO4, 10 mM HEPES, 2 mM glutamine, 11.1 mM glucose, 0.01% trypsin inhibitor, minimal Eagle’s medium amino acid supplement and 0.5% bovine serum albumin. All media used in this study were adequately gassed with 95% O2–5% CO2 and pH adjusted to 7.4.

Rats were sacrificed, and the pancreas was immediately removed and trimmed of fat and mesentery. Five milliliters of the basic medium containing collagenase (1 mg/ml) and 0.1 mM CaCl2 (the medium for dissociation) was injected into the pancreas to make it swell. This swollen pancreas was then minced and incubated in a 25 ml Erlenmeyer flask with reciprocal shaking (120 strokes/min) at 37°C for 10 min. After this first incubation, excess medium was discarded, and 5 ml of fresh dissociation medium was added. The pancreas was incubated again under the above-described conditions for 40 min. The digested pancreas was then mechanically disrupted by aspirating up and down through pipettes with decreasing orifice size. After the disrupted pancreatic tissue was filtered through a nylon sieve (mesh size 0.15 mm), the sieve was rinsed with 10 ml of the basic medium containing 1% BSA and 0.1 mM CaCl2. The filtrate containing pancreatic acini was then centrifuged (50 × g, 4°C, 4 min) and the pellet thus obtained was resuspended with the basic medium containing 4% BSA and 0.5 mM CaCl2 and centrifuged (50 × g, 4°C, 4 min). Finally, pancreatic acini were suspended with HR and preincubated for 30 min before each experimental use.

Morphological observation
The morphological features of the isolated pancreatic acini were examined by phase contrast microscopy and transmission electron microscopy. Phase contrast micrographical studies were directly carried out under a phase contrast microscope (Nikon Diaphoto-TMD). For transmission electron microscopical ex-
aminations, isolated acini were prefixed with 0.1 M KRB buffer containing 2.5% glutaraldehyde, followed by the fixation with 1% OsO₄. The fixed acini were dehydrated with ethanol, inverted in propylene dioxide, and finally embedded in Epon. The ultrathin sections were stained with uranyl acetate and poststained with lead nitrate and then examined by a Hitachi HS-11 electron microscope.

Measurement of viability of pancreatic acini

To evaluate the viability of pancreatic acinar cells, the trypan blue exclusion test and measurement of the leakage of lactic dehydrogenase (LDH) activity were employed. Trypan blue dye dissolved in 0.9% NaCl solution was added to the suspension of pancreatic acini to a final concentration of 0.2%, and unstained cells were counted under a microscope. LDH activities in cells and medium were assayed by the method of Wroblewski (13). The leaked LDH activity was expressed as a percentage of the total initial content in cells.

Determination of enzyme secretion

After the preincubation with reciprocal shaking (60 strokes/min) at 37°C for 30 min, acini were centrifuged and resuspended in fresh HR to adjust the protein concentration of 0.3–0.5 mg protein/ml. Four milliliters of this suspension was transferred to 25-ml siliconized glass flasks and then incubated with reciprocal shaking (60 strokes/min) at 37°C with various agents. Following incubation of various intervals, 1 ml of cell suspension was centrifuged at 10,000 × g by a Beckman microcentrifuge for 20 sec, and the supernatant obtained was subjected to the determination of various digestive enzymes. Enzyme activity determined in the supernatant before incubation was taken as the value at zero time. The net value of secreted enzyme activity obtained after incubation with various drugs was calculated by subtracting the enzyme activity detected in the supernatant before incubation (zero time) from that detected in the supernatant after incubation with drugs. The total activity of each enzyme in the cells before incubation was measured as follows: The pellet obtained at zero time was rinsed with ice-cold 0.9% NaCl, recentrifuged and the same volume of distilled water was added. This sample was homogenized by a Polytron homogenizer and then subjected for the measurements of both enzyme activity and protein content. The enzyme released into the medium during the incubation was expressed as the percentage of total initial content of enzyme activity in pancreatic acini. Amylase activity was assayed by the method of Ceska et al. (14) using the Phadebas blue starch test. Chymotrypsinogen was initially converted to chymotrypsin by bovine trypsin according to the method of Dagorn (15), and the activity of chymotrypsin was assayed by the method of Imondi with a modification using N-benzoyl-L-tyrosyl-p-aminobenzoic acid (BT-PABA) as a substrate (16). Lipase activity was determined by the BALB-DTNB method (17). Protein was measured by the method of Lowry et al. with bovine serum albumin as a standard (18).

Muscarinic receptor binding assay

Muscarinic receptor binding was carried out according to the methods described previously with a minor modification (19, 20) using [³H]quinuclidinyl benzilate ([³H]QNB, 42.6 Ci/mmol) as a radiolabeled ligand for the muscarinic receptor. After the preincubation of acini at 37°C for 30 min, acini (0.05–0.18 mg protein/ml of suspension) in HR without bovine serum albumin were incubated with various concentrations of [³H]QNB at 37°C for 180 min. The total volume used for the receptor binding assay was 4 ml. Specific binding was calculated by subtracting the binding obtained in the presence of 10⁻⁵ M atropine from the total binding determined in the absence of atropine. Each binding assay was performed in triplicate. The reaction was terminated by filtering the cell suspension through a Whatman GF/B filter under vacuum, followed by three times washing with ice-cold 0.9% NaCl solution (total volume: 15 ml). The filter was transferred to a scintilla-
tion vial containing 10 ml scintillation cocktail, and the radioactivity was measured by a liquid scintillation spectrometer.

Statistics
All results obtained were expressed as the mean ± S.E., and Student's t-test was employed to determine statistical significance.

RESULTS

Morphological features of isolated pancreatic acini
Figure 1-A shows a phase microscopic view of the isolated acini. The preparation consisted of single cells and clumps of cells with acinar configuration. No contamination of duct fragments and islets of Langerhans was observed. The transmission electron micrograph of isolated acini revealed that intracellular organellae such as nuclei, mitochondrias, zymogen granules, endoplasmic reticulums and ribosomes appeared to retain their normal structure (Fig. 1-B). The zymogen granules in each cell were localized at the apical site of cells rather than the site opposite to the lumen. These morphological observations clearly demonstrate that the isolated pancreatic acini used in this study possess morphological features typical to pancreatic acinar cells.

Viability of acinar cells
Two types of tests were employed to evaluate the viability of pancreatic acini, namely the activity to exclude trypan blue dye and the leakage of lactic dehydrogenase (LDH) activity from isolated acini into the incubation medium. Figure 2 shows the changes in the viability of isolated acini during incubation in KHB buffer at 37°C. Immediately after the isolation, only less than 10% of the acini was stained by trypan blue dye. Although the proportion of isolated acini excluding trypan blue dye showed a gradual decrease during the examined incubation period, it was found that more than 80% of the isolated acini showed the activity to exclude dye even after 180 min of incubation (Fig. 2-A). Leakage of LDH activity from isolated acini into the incubation medium increased gradually with the time of incubation. However, the leakage of LDH activity was less than 5% of the total LDH activity at 3 hours after the initiation of incubation (Fig. 2-B). Based on these results, it is likely that the isolated acini used in the present study retain good viability.

Characteristics of enzyme release from isolated pancreatic acini by secretagogues
The time course of amylase release from isolated pancreatic acini in the presence or absence of carbachol (10⁻⁶ M) is shown in Fig. 3. The increase in amylase release in the absence of carbachol exhibited a linearity with time of incubation. On the other hand, amylase release in the presence of carbachol (10⁻⁶ M) showed a remarkable increase during the first 30 min of incubation, and the rate of increase was found to be linear until 120 min of incubation. When the carbachol-stimulated secretion of amylase was expressed as the ratio to the value determined in the absence of carbachol, the ratio exhibited its maximum value (about 4 fold of the value without carbachol) at 30 min after the initiation of incubation (Fig. 3). According to these results, amylase release induced by secretagogues was determined during the first 30 min after the addition of secretagogues.

Based on the data that the releases of chymotrypsinogen and lipase from pancreatic acini by carbachol (10⁻⁵ M) became linear 60 and 30 min after the addition of carbachol, respectively, the incubation time for examining the releases of chymotrypsinogen and lipase in the presence of secretagogues was determined at 60 and 30 min after the addition of carbachol, respectively.

Figure 4-A shows the dose-response curve for amylase release stimulated by various concentrations of carbachol. This curve was bell-shaped and the maximal response was observed at 10⁻⁵ M. To examine whether or not the stimulatory effect of carbachol on amylase release from isolated pancreatic acini was mediated by muscarinic receptors, the
Fig. 1. Phase contrast micrograph (A) and transmission electron micrograph (B) of isolated acini from rat pancreas. Scale bar: 0.1 mm (A), 1 μm (B).
effect of atropine on the carbachol-stimulated amylase release was investigated. Atropine inhibited the carbachol-stimulated amylase release in a dose-dependent manner as shown in Fig. 5, and the $ED_{50}$ value for atropine was $1.17 \times 10^{-8}$ M. In addition, other muscarinic agonists such as methacholine and acetylcholine also induced a significant increase of amylase release at the concentration of $10^{-6}$ M. Furthermore, the increase in amylase release induced by these drugs was significantly inhibited by $10^{-5}$ M atropine (Table 1).

The effects of methacholine and bethanechol, muscarinic agonists, on the releases of chymotrypsinogen and lipase were also examined. The release of both enzymes from

Amylase release during incubation (30 min, 37°C) was expressed as a percentage of the total initial content. Each value represents the mean ± S.E. of 6 separate experiments. A) Amylase release in the presence of various concentrations of carbachol. B) Amylase release in the presence of various concentrations of CCK-8.

Fig. 5. Effect of atropine on carbachol-stimulated amylase release from isolated rat pancreatic acini. Pancreatic acini were incubated for 30 min at 37°C with $10^{-5}$ M carbachol and various concentrations of atropine. Each value represents the mean ± S.E. of 4 separate experiments.
isolated acini were significantly stimulated by muscarinic agonists at the concentration of $10^{-6}$ M (Figs. 6 and 7). In addition, the increase of the release of these enzymes was also found to be significantly inhibited by $10^{-5}$ M atropine (Table 2).

Cholecystokinin (CCK) is also known as one of the secretagogues that induces the release of amylase from the pancreas. Therefore, in this study, we have examined the effect of CCK on the releases of chymotrypsinogen and lipase from isolated pancreatic acini. Figure 4B shows the dose-response curve for amylase release in the presence of CCK-octapeptide (CCK-8), a peptide thought to bind to a receptor different from the muscarinic receptor. CCK-8 ($10^{-10}$ M) induced a maximal response, and the dose response curve showed a similar shape to that observed in the presence of carbachol. Similar dose-responses of CCK-8 were obtained in the releases of chymotrypsinogen and lipase.

| Table 1. Effects of muscarinic agonists and atropine on amylase release from isolated rat pancreatic acini |
|---|---|---|
| Drug | Amylase release (percent of control) | 
| | | Atropine (-) | Atropine (+) |
| Carbachol | $10^{-5}$ M | 493.1 ± 55.0 | 88.5 ± 9.1 |
| Methacholine | $10^{-6}$ M | 458.0 ± 35.2 | 95.4 ± 5.8 |
| Acetylcholine | $10^{-6}$ M | 401.5 ± 27.2 | 92.1 ± 7.1 |

Pancreatic acini were incubated for 30 min at 37°C with various drugs. The concentration of atropine was $10^{-5}$ M. Each value is expressed as a percentage of the amylase release without any drugs. Each value represents the mean ± S.D. of 4 to 6 separate experiments. *Atropine $10^{-5}$ M.

| Table 2. Effects of muscarinic agonists and atropine on releases of chymotrypsinogen and lipase from isolated rat pancreatic acini |
|---|---|---|---|
| Drug | Chymotrypsinogen release (percent of control) | Lipase release (percent of control) | 
| | | Atropine (-) | Atropine (+) | Atropine (-) | Atropine (+) |
| Carbachol | $10^{-5}$ M | 359.4 ± 21.8 | 101.5 ± 4.6 | 381.7 ± 42.0 | 103.5 ± 15.1 |
| Methacholine | $10^{-6}$ M | 339.6 ± 6.1 | 98.6 ± 1.0 | 360.9 ± 46.3 | 99.6 ± 2.3 |
| Bethanechol | $10^{-6}$ M | 129.6 ± 2.6 | 100.8 ± 3.7 | 176.6 ± 38.5 | 100.4 ± 8.7 |

Pancreatic acini were incubated for 60 min and 30 min at 37°C to measure the releases of chymotrypsinogen and lipase, respectively. The concentration of atropine was $10^{-5}$ M. Each value is expressed as a percentage of the amylase release without any drugs. Each value represents the mean ± S.D. of 4 to 6 separate experiments. *Atropine $10^{-5}$ M.

Effect of antagonists for muscarinic receptor subtypes on carbachol-stimulated amylase release from isolated pancreatic acini

Effect of pirenzepine (PZ), a M<sub>1</sub> receptor antagonist, and AF-DX 116, a cardio-selective M<sub>2</sub> receptor antagonist, on the carbachol-stimulated amylase release was also investigated. These antagonists exhibited a dose-dependent inhibition on the carbachol-stimulated amylase release (Fig. 8), and the ED<sub>50</sub> values of PZ and AF-DX 116 were found to be 4.39 $\times$ $10^{-6}$ M and 5.06 $\times$ $10^{-5}$ M, respectively.
Fig. 6. Chymotrypsinogen release from isolated pancreatic acini in the presence of carbachol and CCK-8. Chymotrypsinogen release during incubation (60 min, 37°C) was expressed as a percentage of the total initial content. Each value represents the mean ± S.E. of 4 separate experiments. A) Chymotrypsinogen release in the presence of various concentrations of carbachol. B) Chymotrypsinogen release in the presence of various concentrations of CCK-8.

A) Lipase release in the presence of various concentrations of carbachol. B) Lipase release in the presence of various concentrations of CCK-8.
Fig. 8. Effects of pirenzepine (PZ, ▲) and AF-DX 116 (■) on carbachol-stimulated amylase release from isolated rat pancreatic acini. Pancreatic acini were incubated for 30 min at 37°C with 10^{-5} M carbachol and varying concentrations of PZ and AF-DX 116. Each value represents the mean ± S.E. of 4 separate experiments.

Fig. 9. Specific binding of [3H]QNB to isolated pancreatic acini. Pancreatic acini were incubated in HEPES Ringer buffer for 180 min at 37°C with the indicated concentrations of [3H]QNB in the presence or absence of 10^{-5} M atropine. Each value for specific binding was obtained by subtracting non-specific binding from the total binding. Each value represents the mean ± S.E. of 4 separate experiments.

Characteristics of muscarinic receptors of isolated pancreatic acini

Pharmacological characteristics of muscarinic receptors of isolated pancreatic acini were examined using [3H]quinuclidinyl benzilate (QNB) as a radiolabeled ligand. The amount of [3H]QNB specifically bound to pancreatic acini showed a relatively slow increase with the time of incubation and reached a plateau at about 150 min after the addition of [3H]QNB into the incubation medium (data not shown). For measuring the specific binding of [3H]QNB to pancreatic acini as a function of [3H]QNB concentration in the incubation medium, pancreatic acini were incubated in the presence of various concentrations of [3H]QNB (10–2000 pM) at 37°C for 180 min. The specific [3H]QNB binding was found to be saturable with the increase of [3H]QNB concentration (Fig. 9). Scatchard analysis revealed that isolated pancreatic acini used in this study possessed a high affinity binding site with a K_d value of 0.09 nM and a B_max value of 89.3 fmol/mg protein (Fig. 10). Moreover, this [3H]QNB binding to isolated pancreatic acini was dose-dependently inhibited by atro-
pine with an IC$_{50}$ value of $2.56 \times 10^{-9}$ M (Fig. 11). Similarly, the effects of PZ and AF-DX 116 on the $[^3]$H$[^3]$QNB binding was examined. These antagonists for muscarinic subtypes also showed an inhibitory effect on $[^3]$H$[^3]$QNB binding similar to that of atropine, although the IC$_{50}$ values of PZ and AF-DX 116 were $2.90 \times 10^{-7}$ M and $1.21 \times 10^{-6}$ M, respectively (Fig. 12).

Pancreatic acini were incubated in HEPES Ringer buffer for 180 min at 37°C with 0.1 nM of $[^3]$H$[^3]$QNB in the presence of various concentrations of atropine and 0.1 nM of $[^3]$H$[^3]$QNB. Values are given as the mean ± S.E. of 4 separate experiments.
DISCUSSION

In the present study, we have examined the morphological characteristics, the enzyme releases in response to muscarinic cholinergic agents and pharmacological characteristics of muscarinic receptors in rat pancreatic acini isolated by collagenase digestion. Morphological studies using transmission electron microscope demonstrated that isolated pancreatic acini retain intact microscopic features, which were in accordance with previously reported data using isolated pancreatic acini and pancreas in vivo (4, 6, 21, 22). In addition, the acini maintained a good viability as judged by the trypan blue exclusion test and the leakage of LDH activity. Therefore, it has been concluded that these isolated pancreatic acini are useful for investigating its physiological functions including the effect of muscarinic stimulation on digestive enzyme release and the characteristics of the muscarinic receptors of the pancreatic acini.

The ratio of carbachol-stimulated amylase release to non-stimulated (basal) amylase release was found to be about 4.0 at 30 min after the addition of muscarinic agonists, which is in good agreement with the previously reported data (6, 23). In this study, the responsiveness of enzymes release (amylase, chymotrypsinogen, and lipase) to carbachol in isolated pancreatic acini showed a biphasic pattern. It is not clear why such a biphasic pattern of carbachol-stimulated enzymes release was observed in isolated acini. Williams et al. proposed that this phenomenon might be due to a rapid decline in the rate of amylase release following an initial few minutes of stimulation (24) and termed it "desensitization" or "tolerance" (6). On the other hand, Barlas et al. proposed the concept of "restricted stimulation" for the similar phenomenon observed in their experiments, in which amylase release induced by CCK-8 decreased with the highest concentration of CCK-8 (25). It was noteworthy that the patterns of the releases of chymotrypsinogen and lipase in response to CCK-8 were similar to that of amylase in the present study. Two hypotheses about pancreatic exocrine secretion, parallel secretion and non-parallel secretion, have been proposed (26, 27). However, from the results demonstrated...

Fig. 12. Effects of pirenzepine (PZ, △) and AF-DX 116 (■) on [3H]QNB binding to isolated rat pancreatic acini. Pancreatic acini were incubated in HEPES Ringer buffer for 180 min at 37°C with 0.1 nM of [3H]QNB in the presence of various concentrations of PZ and AF-DX 116. Each value represents the mean ± S.E. of 4 separate experiments.
in this study, it has been suggested that pancreatic exocrine cells have the ability to secrete digestive enzymes such as amylase, chymotrypsinogen and lipase in a similar fashion to the secretion of enzymes induced by the stimulation by agonists for muscarinic and CCK receptors.

The present study and other reports have clarified that muscarinic receptors are indeed present on rat pancreatic acini (19, 20). The association of [3H]QNB with muscarinic receptors of pancreatic acini was slow, and more than 150 min was required to attain saturation. On the other hand, [3H]N-methylscopolamine ([3H]NMS), a radiolabeled ligand for muscarinic receptors, bound rapidly to pancreatic acini, and an equilibrium state of binding was observed within 60 min after the addition of this ligand (data not shown). This difference in binding characteristics between [3H]NMS and [3H]QNB may be due to the hydrophobic property of the QNB molecule (28). Under the equilibrium condition, the specific binding of [3H]QNB followed a simple isotherm saturation, and the Scatchard plot was linear. The values of $K_d$ and $B_{max}$ for [3H]QNB binding to pancreatic acini obtained in this study agreed well with those found in previous reports (29, 30). The linearity of the Scatchard plot of [3H]QNB binding to isolated pancreatic acini is considered to be evidence for the presence of a single class of binding sites. Recently, the concept of subtypes of muscarinic receptors has been proposed. In fact, the presence of subtypes in muscarinic receptors ($M_1$ and $M_2$) has been detected using new muscarinic antagonists (31–33). The pancreatic acini was also found to have a low affinity for pirenzepine (PZ), an antagonist for the $M_1$ receptor, which suggests the presence of other subclasses of muscarinic receptors on pancreatic acini (34, 35). In recent studies, PZ, a $M_1$ antagonist, and AF-DX 116, a $M_2$ antagonist, have been developed to analyze the subclass of muscarinic receptor involved in pancreatic enzyme release (36, 37). In the present study, the order of $IC_{50}$ values of these muscarinic antagonists for [3H]QNB binding and carbachol-stimulated amylase release was found to be as follows: atropine < PZ < AF-DX 116; These results are in good agreement with the data previously reported (35, 37). Although pancreatic acini showed a low affinity to pirenzepine, which suggested the presence of $M_2$ receptors, AF-DX 116 showed a less significant inhibitory effect on carbachol-stimulated amylase secretion than pirenzepine. This may be due to the high cardio-selectivity of AF-DX 116 (36, 37).

Pancreatic acinar cells have capacities to secrete digestive enzymes such as amylase, chymotrypsinogen and lipase in response to muscarinic and CCK receptor activation. It is noteworthy that pancreatic acini prepared by collagenase treatment exhibited the secretory responses of these enzymes to muscarinic and CCK receptor agonists. Therefore, it is concluded that the isolated pancreatic acini used in this study have exocrine functions similar to pancreatic acinar cells in vivo. These results also suggest that isolated pancreatic acini may be useful for analyzing the mechanism of pancreatic exocrine secretion coupled with muscarinic and CCK receptors.
