ABSTRACT—We examined the relationship between ozone (O₃)-induced airway hyperresponsiveness (AHR) and inflammation in guinea pigs. Inhalation of methacholine (MCh) was adopted in the time course study of AHR that was assessed by measuring pulmonary inflation pressure after O₃ exposure (3 ppm, for 2 hr) because the degree of AHR detected by inhalation of MCh was greater than that detected by i.v. administration. AHR was detected up to 5 hr after O₃ exposure and was not observed at 24 and 48 hr. In the bronchoalveolar lavage (BAL) study, the numbers of neutrophils, eosinophils, lymphocytes and macrophages in BAL fluid (BALF) reached maximum at 24 hr or later. On the other hand, the number of airway epithelial cells in the BALF significantly increased at 2 and 5 hr. In the histological study, disorder and impairment of the airway epithelium in the trachea and lung were observed at 2 and 5 hr. Changes in the airway epithelium were recovered at 48 hr, although an increase in leukocytes was observed in the lung. These results indicate that O₃-induced AHR in guinea pigs is most probably associated with impairment of the epithelium rather than with infiltration of inflammatory cells in the airway.

Keywords: Ozone, Airway hyperresponsiveness, Inflammatory cell, Epithelial cell

Airway hyperresponsiveness (AHR) is an important pathophysiological feature of asthma. Accordingly, it is very essential to elucidate the process of AHR and to find a way to improve it. To date, allergen (1, 2)-, virus (3, 4)-, Sephadex beads (5, 6)-, platelet activating factor (7, 8)-, endotoxin (9)- and air pollutant (10)-induced AHR models in various animals are widely used by many laboratories to clarify the mechanism of AHR. However, it has not been elucidated in detail because it is a very complicated process.

It is well known that ozone (O₃), an air pollutant, and exposure to humans (11), dogs (12), rats (13), guinea pigs (14) and other animals can cause transient AHR and airway inflammation. Therefore, O₃-induced AHR is used as a tool for investigating AHR. It is said that O₃-induced AHR is due to 5-lipoxygenase metabolites (15), endogenous tachykinin (16) and other factors. On the other hand, some reports indicated that infiltration of neutrophils into the airway lumen was associated with O₃-induced AHR (17-19), but another reports have denied this (13, 20).

In this study, we examined the effect of inflammatory cell infiltration and morphological change in the airway mucosal layer on O₃-induced AHR in guinea pigs using bronchoalveolar lavage (BAL) and histological study in the airway.

MATERIALS AND METHODS

Animals
Male Hartley guinea pigs (Japan SLC, Inc., Hamamatsu), weighing 330 to 740 g, were used. These animals were housed in an environmentally controlled room (temperature, 23±2°C; humidity, 55±5%; illumination time, from 7:00 to 19:00) with food and water available ad libitum for 1 week prior to the experiment.

Chemicals
The following chemicals were used: pentobarbital sodium (Abbott, North Chicago, IL, USA), gallamine triethiodide and HEPES (Sigma, St. Louis, MO, USA), methacholine chloride (MCh; Nacalai Tesque Co., Ltd., Kyoto), Hanks (Nissui Pharmaceutical Co., Ltd., Tokyo), heparin (Mochida Pharmaceutical Co., Ltd.,
Giemsa's stain solution (Merck, Rahway, NJ, USA). These reagents were laboratory grade or better.

O<sub>3</sub> exposure

Animals in an acrylic chamber (29 x 19 x 25 cm) inhaled O<sub>3</sub> produced by an O<sub>3</sub> generator (OZX-02; Silver Seikou, Tokyo) for 2 hr. During O<sub>3</sub> exposure, it was closely monitored by an O<sub>3</sub> detector (SOZ-3000 and -3100; Seki Electronics, Tokyo) to keep its concentration at 3 ppm. Animals in the control group not exposed to O<sub>3</sub> were placed in cages until they were anesthetized for measuring airway reactivity.

Measuring of airway reactivity

The O<sub>3</sub>-exposed and control animals were anesthetized with pentobarbital sodium (60 mg/kg, i.p.) and artificially ventilated by a Harvard 683 respirator (10 ml/kg, 60 strokes/min) through a tracheal cannula. Spontaneous respiration was stopped by gallamine triethiodide (5 mg/kg, i.v.). Pulmonary inflation pressure (PIP) as the index of airway reactivity was measured by a pressure transducer (LPU-0.1; Nihon Kohden, Tokyo) connected to a tracheal cannula.

Administration of spasmogen

To assess O<sub>3</sub>-induced AHR, the animals were challenged by MCh, as a spasmogen, through i.v. administration (0.3 – 10 μg/kg) via the lateral saphenous vein or by inhalation. On inhalation challenge of MCh, the tracheal cannula connected to a container (29 x 50 mm) that contained 5 ml of MCh saline solution (0.1–1000 μg/ml); and under the above condition of respiration, aerosol was generated with an ultrasonic nebulizer (TUR-3000, Nihon Kohden) for 2 min.

The index of AHR

The provocative dose and the concentration of MCh that caused a 5 cmH<sub>2</sub>O increase in PIP (ΔPIP) was expressed as PD<sub>5</sub> by i.v. administration and as PC<sub>5</sub> by inhalation. As the index of AHR, logPD<sub>5</sub> and logPC<sub>5</sub> values were determined.

Bronchoalveolar lavage (BAL)

Animals were sacrificed by means of intraperitoneal injection of pentobarbital sodium (100 mg/kg, i.p.) 2, 5, 24, 48 and 192 hr after O<sub>3</sub> exposure. The trachea was immediately cannulated, and bronchoalveolar lavage fluid (BALF) was obtained by injection of 10 U/ml heparin and 25 mM HEPES-containing sterile Hanks solution (pH 7.2, volume: 5 ml x 5/animal, Hanks(+)) warmed to 37°C into the trachea. The obtained BALF was centrifuged at 400 x g for 5 min at 4°C. The obtained precipitate was suspended to 1 ml/animal of Hanks(+), and the number of total cells in 20 μl of suspension was counted by a Sysmex Platelet Counter (PL-110; Toh-a Medical Electronics, Co., Ltd., Kobe). A 20-μl aliquot of the cell suspension was used for a differential count that was made on a smear prepared and stained by Giemsa's stain solution. The numbers of neutrophils, eosinophils, lymphocytes, macrophages and epithelial cells were counted by a light microscope at a magnification x 1,000. Airway epithelial cells were discriminated by recognition of the cobblestone appearance typical of epithelial cells in light microscopic examination.

Histological study

The animals were anesthetized with pentobarbital sodium (30 mg/kg, i.p.), and were transcardially perfused with 10% phosphate-buffered formalin (PBF) for 5 min. The trachea and lung were then isolated from control and O<sub>3</sub>-exposed animals 2, 5 and 48 hr after O<sub>3</sub> exposure. Isolated trachea and lung were fixed in 10% PBF, embedded in paraffin, cut and stained with hematoxylin-eosin, and they were observed using a light microscope.

Statistical analyses

All results are expressed as the mean±S.E.M. except for the data from the histological study. Comparisons of the mean values were made by Student's t-test or analysis of variance followed by the Tukey-Kramer's method.

RESULTS

Assessment of O<sub>3</sub>-induced AHR by i.v. administration of MCh

The airway reactivities in air (control)- or O<sub>3</sub>-exposed guinea pigs were investigated by i.v. administration of MCh 2 hr after air or O<sub>3</sub> exposure, and the results are shown in Fig. 1 and Table 1. I.v. administration of MCh dose-dependently elevated PIP from 3 rig/kg, i.v. in the control. O<sub>3</sub> exposure tended to produce a leftward shift in the MCh dose-response curves (Fig. 1), while logPD<sub>5</sub> values were not significantly lower compared with the control (Table 1).

Assessment of O<sub>3</sub>-induced AHR by inhalation of MCh

The airway reactivities in air (control)- or O<sub>3</sub>-exposed guinea pigs were investigated by inhalation of MCh, and the results are shown in Fig. 2 and Table 1. Inhalation of MCh concentration-dependently increased PIP from 3 μg/kg, i.v. in the control. O<sub>3</sub> exposure tended to produce a leftward shift in the MCh dose-response curves (Fig. 2). LogPC<sub>5</sub> in the O<sub>3</sub>-exposed groups were significantly lower compared with the control (Table 1).

Animals inhaled 3 ppm of O₃ for 2 hr. Pulmonary inflation pressure (PIP) was used as the index of bronchoconstriction. PD₅ and PC₅ are defined as the provocative dose (ng/kg, i.v.) and provocative concentration (ng/ml, 2 min inhalation) of methacholine that increased PIP by 5 cmH₂O, respectively. Each value represents the mean±S.E.M. of 4 experiments. **P<0.01, statisically significant compared with the O₃(-) group by Student’s t-test.

Time course of AHR after O₃ exposure

To investigate the persistence of AHR caused by 3 ppm of O₃ exposure for 2 hr, the time course of airway reactivity to inhalation of MCh after O₃ exposure was studied, and the results are shown in Fig. 3 and Table 2. The concentration-response curve to MCh was significantly shifted to the left at 2 and 5 hr, but not at 24 and 48 hr (Fig. 3). The values of logPC₅ in O₃-exposed guinea pigs were also significantly lower at 2 and 5 hr, but not at 24 and 48 hr (Table 2), compared with the control. Namely, these data indicated that O₃-induced AHR was diminished from 5 to 24 hr.

**BAL after O₃ exposure**

The results of the BAL study are shown in Figs. 4 and 5. The cells recovered in the BALF were classified into neutrophils, eosinophils, lymphocytes, macrophages and epithelial cells; and the number of cells in each cell population was counted under a light microscope following staining. The number of neutrophils slightly increased 24 hr after O₃ exposure, but this was not significant. The number of eosinophils and lymphocytes at 48 hr was 26.3(±5.8) x 10⁵ and 3.4(±0.6) x 10⁵ cells/BALF/animal, respectively. These were significant increases compared with the control (6.7(±4.3) x 10⁵ and 0.4(±0.1) x 10⁵ cells/BALF/animal, respectively). Macrophages were increased from 24 hr, reaching a maximum at 96 hr (110.6(±17.6) x 10⁵ cells/BALF/animal). This increase was recovered at 192 hr to the control level. Significant increases in epithelial cells compared with the control (0.9(±0.2) x 10⁵ cells/BALF/animal) were recognized at 2 and 5 hr (7.0(±2.0) x 10⁵ and 15.1(±3.4) x 10⁵ cells/BALF/animal, respectively), but epithelial cells did not significantly increase after 24 hr and later on.

**Histological study in central and peripheral airway**

In the BAL study, epithelial cells in the BALF significantly increased 2 and 5 hr after O₃ exposure when AHR was detected. Accordingly, the preparations of the trachea and the lung at 2, 5 and 48 hr and in the control were observed under a light microscope, and the results are shown in Figs. 6 and 7. Shedding, vacuolation and derangement of the epithelium in the trachea and the lung...
DISCUSSION

Some researchers (17–19) have emphasized the association between O₃-induced AHR and infiltration of inflammatory cells, especially neutrophils. Weideman and Schlesinger (21) reported that neutrophils in humans and rabbits were activated to change eicosanoid metabolism following O₃ exposure in vitro. However, there have been some arguments against the involvement of inflammatory cells in O₃-induced AHR (13, 20). Accordingly, it remained necessary to investigate how inflammatory cells were associated with O₃-induced AHR. In this study, we assessed the transient AHR observed by administration of MCh after 3 ppm of O₃ exposure for 2 hr and investigated the association between O₃-induced AHR and airway inflammation.

Fig. 5. Changes in the number of airway epithelial cells in BALF after O₃ exposure in guinea pigs. Each column represents the mean±S.E.M. of 7 experiments. *P<0.05, **P<0.01, statistically significant compared with the control group by one-way ANOVA (Tukey-Kramer’s method).

Fig. 6. Representative photographs of tracheal mucosa in air- and O₃-exposed guinea pigs. a: Air-exposed (control), b: 2, c: 5 and d: 48 hr after O₃ exposure. Derangement and impairment of the tracheal epithelium were recognized in b and c. The recovery of the epithelium was observed in d. Magnification ×150.
Dose- or concentration-response curves to MCh were shifted to the left by O$_3$ exposure (Figs. 1 and 2). The degree of AHR from the values of logPD$_5$ and logPC$_5$, however, was detected by inhalation of MCh but not by i.v. administration (Table 1). Yeadon and Payne (22) reported that inhalation of spasmogen was available for AHR detection but not i.v. administration in guinea pigs exposed to 3 ppm of O$_3$ for 30 min. Therefore, it is conceivable that O$_3$ acted at the airway luminal side. Since then, we adopted inhalation of MCh to detect AHR, although AHR has been assessed by i.v. administration of spasmogens in some laboratories.

It is well understood that O$_3$-induced AHR and inflammation are transient (23). Because some reports suggested that O$_3$-induced AHR is associated with infiltration of inflammatory cells including neutrophils in the airway (17–19), we first examined the time course of AHR after O$_3$ exposure. In this study, the AHR was observed up to 5 hr, and it was already diminished from 24 hr (Fig. 3 and Table 2). At the same time, the time course study of changes in the numbers of infiltrated inflammatory cells was performed by BAL. Infiltration of inflammatory cells was not recognized up to 5 hr when AHR was detected (Fig. 4), and it increased or reached a maximum at 24 hr or later when AHR was already diminished. However, the number of epithelial cells in the BALF significantly in-

Fig. 7. Representative photographs of peripheral airway in the lung in air- and O$_3$-exposed guinea pigs. a: Air-exposed (control), b: 2, c: 5 and d: 48 hr after O$_3$ exposure. Derangement and impairment of the epithelium were recognized in b and c. The recovery of the epithelium was observed in d. An increase in leukocytes was recognized in d, but not in a, b and c. Magnification $\times$75.
creased up to 5 hr when AHR was detected (Fig. 5). In the histological study, the preparations of the trachea and lung were observed by a light microscope (Figs. 6 and 7). Disorder and impairment of epithelial cells were observed, and inflammatory cells were not recognized in the mucosal and submucosal layers at 2 and 5 hr. In the preparations at 48 hr, the epithelium was recovered in the trachea and lung, and inflammatory cells in the lung increased. These results indicate the conflict between O₃-induced AHR and increase in inflammatory cells in the airway are consistent with the results of Evans et al. (13) who used rats, and the impairment of the airway epithelium coincided with the persistence of AHR. As to the role of epithelial cells, they are involved in the metabolism and the breakdown of endogenous and exogenous spasmogens (24), the protection against irritants entering into the airway from one’s external environment (24 - 27), the control of airway smooth muscle contraction (24, 28, 29), excretion of sputa and foreign bodies (24, 30) and so on. On the other hand, it was demonstrated that O₃ injured the lipid layer of the cell membrane by peroxidation in vitro (31). Namely, it is likely that O₃ directly injured the epithelial cells by peroxidation and that AHR appeared following the loss of epithelial cell functions. Therefore, we can suppose that spasmogens fail to be metabolized by epithelial cells and/or easily reach the smooth muscle in the airway tissue in the mechanism of O₃-induced AHR. Furthermore, the active sites (for example, disclosure of C-fiber, etc.) for spasmogens under the mucosal layer may appear simultaneously following the shedding of the epithelium.

Our results indicate that O₃-induced AHR may be caused by loss of normal epithelial cell functions, but not by infiltration of inflammatory cells into the airway. It is said that many mediators are important for O₃-induced AHR (15, 16). Further studies of the origin and the influence of those mediators will be necessary to define the nature of O₃-induced AHR.
