Abstract. [Purpose] The present literature review was conducted on the use of different measures for the evaluation of balance in patients with Parkinson's disease. [Materials and Methods] The PubMed, Bireme, SciELO, Lilacs, and PEDro electronic databases were searched for relevant studies. [Results] The searches initially led to the retrieval of 3,623 articles, 540 of which were potentially eligible after limiting the search to clinical trials published in the last five years. A total of 264 duplicates were removed, and 276 articles were excluded based on their titles and abstracts. The full texts of 84 articles were analyzed, and only those with a PEDro score higher than four points (n=25) were included in the review. [Conclusion] Different methods, such as scales, tests, and equipment, are used for the evaluation of balance in patients with Parkinson's disease. More than one measure has been employed in most studies, and there is no consensus on a single precise measure for the evaluation of balance in this population.

Key words: Parkinson's disease, Balance, Postural control

(This article was submitted Dec. 21, 2015, and was accepted Feb. 15, 2016)

INTRODUCTION

Parkinson's disease (Parkinson's) is a progressive, chronic, neurodegenerative disease¹⁾ stemming from the atrophy of grey matter. It is estimated that 10 million individuals around the world suffer from Parkinson's, and this figure is expected to double by the year 2030²⁾. The prevalence of Parkinson's ranges from 0.3% among individuals aged less than 60 years to 1% among those aged 60 or older³⁾. The progressive nature of the disease causes both motor and non-motor alterations. The main motor alterations are associated with the risk of falls, which leads to a sedentary lifestyle and the reduction in activities of daily living exerts a negative impact on clinical aspects¹⁻⁵⁾.

The main clinical manifestations of Parkinson's are shaking, stiffness, slowness of movement, postural alterations, and stooped gait, leading patients to adopt a flexed posture due to the dominance of pro-gravitational muscles, with forward leaning of the head, the chin tilted toward the thorax, kyphotic thorax, protracted shoulders, the arms rotated internally, and, flexion of the hips, knees, and elbows, which projects the body forward, compromising postural orientation and leading to

impaired balance⁶⁾. All these postural changes, together with other alterations, lead to postural instability, which is considered one of the main characteristics of patients with Parkinson's. This instability leads to a progressive reduction in both static and dynamic balance, affecting one's ability to remain standing without support or even sit down.

Researchers believe that postural instability is related to the loss of the capacity to control intentional movements of the center of body mass on the support base during activities that involve the transfer of weight. Many individuals with Parkinson's demonstrate inadequate interactions among the vestibular, visual, and proprioceptive systems, with consequent changes in the biomechanics of the body⁷⁾.

The motor rehabilitation process for patients with Parkinson's is normally directed toward static and functional balance training to provide greater interactions with the surrounding environment through treadmill training⁸⁾, balance training involving virtual reality programs⁹⁾, the combination of dance and motor training¹⁰⁾, etc. A set of assessment measures to determine the effects of particular interventions has been validated and reported in literature¹¹⁾. Assessment measures are important for analysis of functional changes in all stages of the disease and are particularly sensitive with regard to the evaluation of therapeutic intervention¹²⁾. The Unified Parkinson's Disease Rating Scale (UPDRS)¹³⁾, Berg Balance Scale, Timed Up and Go Test¹⁴⁾, Six-Minute Walk Test (6WMT), 10-Meter Walk Test (10MWT)¹⁵⁾, and a force plate to determine the center of pressure¹⁶⁾ are among the measures used for the evaluation of balance. Moreover, a combination of different measures previously used in controlled clinical trials is often employed.

The aim of the present study was to perform a systematic review of the literature for the analysis of different measures used in the evaluation of balance in patients with Parkinson's disease.

MATERIALS AND METHODS

The PubMed (National Library of Medicine), BVS Bireme, SciELO, LILACS and PEDro electronic databases were searched for relevant studies addressing balance in patients with Parkinson's disease. For this purpose, the following combinations of keywords were used: Parkinson's disease and balance evaluation, Parkinson Disease and balance alterations, Parkinson Disease and balance change, Parkinson Disease and change in balance, Parkinson Disease and Balance Control and Parkinson Disease and Postural Control Balance. The search was limited to randomized controlled, clinical trials published in the previous five years (inclusion criteria).

The searches initially led to the retrieval of 3,623 articles, 540 of which were potentially eligible based on the inclusion and exclusion criteria. A total of 264 duplicates were removed, and 276 articles were excluded based on their titles and abstracts. The full texts of 84 articles were analyzed, with the inclusion of only those that met the eligibility criteria and had a PEDro score higher than four points. Thus, 25 studies were selected for the present systematic review (Fig. 1).

RESULTS

Table 1 displays the PEDro scores of the 25 studies that met the eligibility criteria and were included in the present systematic review. Diverse methods for the evaluation of balance in individuals with Parkinson's were used in studies with different intervention protocols and comparisons between the experimental and control groups (Table 2).

DISCUSSION

In the context of chronic neurological disorders, efforts are made to diminish physical difficulties and allow affected individuals to perform activities of daily living with the greatest possible efficiency and independence³⁸⁾. Thus, assessment tools and specific measures that address more generic aspects, such as muscle strength, range of motion, functioning, and im-

provements in quality of life, are needed for individuals with Parkinson's. It is important for assessment methods to analyze functional changes in all stages of the disease and to be particularly sensitive in the evaluation of therapeutic interventions³⁹⁾.

Among the specific Parkinson's classification measures used in the studies analyzed, the UPDRS is a validated scale that provides an objective perspective and allows the classification of individuals with Parkinson's. The UPDRS is also widely used by physiotherapists for the evaluation of balance in clinical practice, as it has specific items for the assessment of this characteristic. The scale was found to be precise and sensitive according to the results of 14 articles analyzed in the present systematic review, the study populations of which were subject to different intervention protocols⁴⁰⁾. The scale was validated for the population with Parkinson's and, in contains items for the assessment of balance. Volpe et al. ⁴¹⁾ conducted a study involving 24 patients with Parkinson's allocated to two groups and assessed balance using the UPDRS. Regarding the motor skills section of the scale, the authors found a significant improvement in the experimental group (dance) in comparison with the control group (conventional physical therapy).

Eleven studies included in the present review used the Berg Balance Scale for the assessment of balance. This scale is composed of 14 tasks that are common in daily living. Each item is scored from 0 to 4 points, with a maximum score of 56

points. The points are based on the time for which a position is held, the distance to which the upper limb is capable of reaching out in front of the body, and the time required to complete each task⁴²⁾. This is a fast, precise assessment tool for detecting changes in balance among individuals with Parkinson's. In a previous systematic review with meta-analysis, Chih-Hsuan Chou et al.⁴³⁾ found that a reduction in the gait velocity score on the Berg Balance Scale was correlated with impairment regarding the performance of activities of daily living.

The Timed Up and Go Test is used to quantify functional mobility based on the time (in seconds) required to perform the task of standing up from a chair (seat approximately 46 in height and armrests 65 cm in height), walking three meters, turning around, returning to the chair, and sitting down again⁴²⁾. This measure has a specific relationship with gait speed and functional mobility. In the population studied, the Timed Up and Go Test is a good predictor of the risk of falls. Although it was not specifically designed for the assessment of balance, the importance of this measure to the evaluation of dynamic balance related to mobility was evident in the studies analyzed in the present review. In a systematic review with meta-analysis involving 53 studies, Schoene et al.⁴⁴⁾ found that the Timed Up and Go Test was a sensitive assessment tool for the evaluation of gait stability and balance in more than 50% of the studies, which is in agreement with the findings of the present systematic review.

A large portion of the studies employed three or more assessment tools, which were always accompanied by tests and equipment. Several studies have addressed the use of assessment measures for the evaluation of balance among individuals with Parkinson's with the aim of designing interventions that favor an improvement in quality of life and a reduction in the risk of falls. Thus, the studies analyzed evaluated individuals in a complex fashion with functional approaches that were adaptable to the needs of such patients.

The present review shows that a variety of different assessment tools are used for the evaluation of balance in patients with Parkinson's disease, such as scales, tests, and equipment. The majority of studies employed more than one measure, and there is no consensus regarding a single, precise assessment tool for the evaluation of balance in this population.
