Abstract. Transgenic rats show spermatid-specific ectopic expression of the reporter gene, herpes simplex virus type 1 thymidine kinase (HSV1-TK), in the testes and have demonstrated male infertility. However, the disruption of spermatogenesis and the underlying molecular mechanisms in these transgenic animals have not been well clarified. In this study, light and electron microscopic observations were performed to characterize the morphological changes in the testes. To explore the molecular mechanisms of male infertility in the HSV1-TK transgenic rat, cDNA microarray and quantitative real-time PCR analyses were performed. The seminiferous tubules of 3-month-old transgenic rats showed morphological alterations including seminiferous epithelial sloughing, vacuolization, and degeneration of spermatogenic cells, suggesting a failure of Sertoli-germ cell interaction. Components of the epididymal lumen from transgenic rats included abnormal spermatocytes, degenerating round spermatids and abnormal elongated spermatids indicating an appearance of direct impairment of spermiogenesis. cDNA microarray and real-time PCR analyses revealed significant changes (P<0.05) in the gene expression level in six genes, testin, versican, mamdc1, fgf7, ost1 and cnol7. Among them, testin drew most of our attention, since the testin gene is a sensitive marker for disruption of Sertoli-germ cell adhesion. Thus, our results suggest that the accumulation of HSV1-TK in the spermatids not only directly interferes with spermiogenesis but also disrupts spermatogenesis through a disruption of Sertoli-germ cell adhesions. It is important to explore the testicular actions of the HSV1-TK protein in transgenic experimental models and thereby gain clues to find an appropriate treatment for HSV-infected patients exhibiting human male infertility, as has been recently observed.

Key words: HSV1-TK, Infertility, Spermatogenesis, Testin, Transgenic rat

A suicide gene system, herpes simplex virus type 1 thymidine kinase (HSV1-TK) and its specific substrate, ganciclovir, is widely used for cancer therapy [1, 2]. However, previous investigators also reported that HSV1-TK proteins are likely to play a toxic role in the developing mouse male germ cells in the absence of the nucleoside analog, ganciclovir, to induce defects in cell proliferation [3–6]. The major histological defects of HSV1-TK transgenic mice appeared to be an abnormal nuclear morphology of elongating spermatids and electron microscopy observation disclosed insufficient chromatin condensation and abnormal acrosome structures [4]. Al-Shawi et al. demonstrated that truncated TK polypeptides were translated mainly in the haploid spermatids by a cryptic TATA box-independent promoter and that the severity of male infertility depended on the level of enzymatic activity of HSV1-TK produced [5]. However, precise morphological analyses of the seminiferous tubules of HSV1-TK transgenic mice have not yet been reported.

We previously reported that HSV1-TK transgenic rats also show male infertility by the ectopic spermatid-specific ectopic expression of HSV1-TK gene [7]. We have identified the testis-specific transcription start site of the HSV1-TK gene to produce two types of truncated TK polypeptides that retain enzymatic activity [8]. These TK molecules were accumulated in the postmeiotic spermatids, resulting in disruption of spermatid-stage-specific maturation in young transgenic rats and leading to an age-dependent apoptotic loss of germ cells in adult transgenic rats [8].

Although it is well known that HSV1-TK transgenic animals suffer from male infertility, the molecular mechanisms underlying the disruption of spermiogenesis by ectopic expression of the HSV1-TK gene in postmeiotic spermatids have not yet been clarified. Furthermore, the mechanisms leading to apoptotic germ cell loss by HSV1-TK expressed in spermatids are largely unknown. To better understand the severity and toxic role of HSV1-TK in the spermatogenesis injury caused by HSV1-TK, we performed detailed morphological
observations and cDNA microarray analyses. We observed severe dysmorphogenesis in the seminiferous epithelium and epididymal lumen by transmission electron microscopy in 3-month-old transgenic rats and significant changes in the expression of genes related to Sertoli-germ cell adhesions.

Materials and Methods

Experimental animals

HSV1-TK transgenic rats were generated using Fischer 344 rats [8]. Since the produced transgenic rats showed male infertility, heterozygote offspring were obtained by crossing a transgenic female rat with a normal male rat. The animals were individually housed in standard plastic rodent cages in a temperature-controlled environment with standard rat diet and water available ad libitum in a 12-h light/dark cycle [9]. The experimental procedures were approved by the Institutional Animal Care and Use Committee of Meiji University.

Light microscope and transmission electron microscopy (TEM)

The testes and cauda epididymides were isolated from wild-type and transgenic rats at 3 months (each n=2) of age and fixed overnight in 2.5% glutaraldehyde and 0.05 M phosphate buffer (PB; pH 7.4) at 4°C. The samples were washed in 0.1 M PB and fixed in 1% osmium tetroxide/0.05 M PB for 3 h at 4°C. After fixation, the samples were embedded in epoxy resin, and semi-thin (1 µm) and thin (75 nm) sections were cut with an ultramicrotome. The semi-thin sections were stained with toluidine blue for light microscopic examination (BZ-8000; Keyence, Osaka, Japan). The thin sections were dehydrated with serial graded ethanol and acetone and embedded in Epon, followed by staining with uranylacetate, post-staining with lead citrate and analysis by TEM (JEOL JEM1200EX2 electron microscopy, Tokyo, Japan) at an accelerating voltage of 80 kV.

Total RNA preparation

Testes from 3-month-old wild-type and transgenic rats (each n=4) were homogenized in Isogen RNA extraction reagent (Nippon Gene, Tokyo, Japan) with a Polytron homogenizer for 15 sec, and total RNA was prepared from homogenized tissue according to the manufacturer’s instructions. Residual DNAs were digested with RQ1 RNase-Free DNase (Promega, Madison, WI, USA).

cDNA microarray

cDNA microarrays were performed using a custom analysis service (Kurabo Industries, Osaka, Japan), which was an authorized service provider using the Affymetrix array (Affymetrix Japan, Tokyo, Japan). In brief, the quality of RNA samples was checked using a 2100 Bioanalyzer (Agilent, Santa Clara, CA, USA). Ten micrograms of total RNA, a mixture of 2.5 µg from each of four individuals, was subjected to microarray hybridization using the GeneChip Rat Genome 230 2.0 Array (Affymetrix), which consists of over 31,000 probe sets and represents over 28,000 well-substantiated rat genes. Raw intensity data from the GeneChip array were analyzed with GeneChip Operating Software (Affymetrix).

Real-time PCR

Real-time PCR was performed. Briefly, 3 µg total testis RNA from 3-month-old wild-type and transgenic rats (each n=4) was reverse-transcribed using PrimeScript Reverse transcriptase (Takara Bio., Siga, Japan) to confirm the results of cDNA microarray. cDNAs were analyzed in a 20 µl reaction volume containing a set of primers (Table 1) and 10 µl of SYBR Green PCR Master Mix (Toyobo, Osaka, Japan) using a 7500 Real-Time PCR System (Applied Biosystems, Foster, CA, USA) according to the manufacturer’s recommendations. The relative expression level of each gene was normalized and quantified to that of TATA-box binding protein (TBP) as an internal control using RQ software (Applied Biosystems).

Results

Ultrastructural analysis of seminiferous tubules and germ cells

Normal spermatogenesis was confirmed by light microscopic observation of the seminiferous tubules and the epididymides of 3-month-old wild-type rats (Fig. 1A and B). In contrast, transgenic rats revealed particular morphological alterations both in the seminiferous tubules and the epididymides (Fig. 1C and D). These disorders included a lower population of spermatogenic cells (spermatagonia, spermatocytes and round and elongated spermatids) in the seminiferous tubules (Fig. 1C) and fewer spermatooza in the lumen of the
Fig. 1. Morphological alterations in 3-month-old transgenic rats. Toluidine blue-staining was performed for seminiferous tubules (A and C) and cauda epididymides (B and D) of wild-type (A and B) and transgenic rats (C and D). Vacuoles were visible in tubules (C, arrowheads), and degenerating spermatogenic cells were frequently observed (C, arrows). Consequently, a large number of immature and degenerating spermatogenic cells were sloughed into the lumen of seminiferous tubules (C, asterisk) and were eventually pooled in the epididymis (D).

epididymis (Fig. 1D) than in the wild-type rats (Fig. 1A and B). In addition, vacuolization in the seminiferous epithelium (Fig. 1C, arrowhead), degenerating spermatogenic cells (Fig. 1C, arrow), many exfoliated immature and degenerated spermatogenic cells (Fig. 1C, asterisk) and accumulation of immature spermatogenic cells in the epididymides (Fig. 1D) were observed.

We then performed ultrastructural analysis of seminiferous tubules to identify the spermatogenic cell type using TEM. When compared with the results of the 3-month-old wild-type rats (Fig. 2A–C), massive vacuoles were observed within the seminiferous epithelium of transgenic rat testes (Fig. 2D and E, asterisk). While spermatocytogenesis and meiosis were confirmed, degenerating spermatocytes were frequently observed in the seminiferous tubules of the transgenic rats (Fig. 2E and F, arrowhead). Moreover, in the lumen of the seminiferous tubule, elongated spermatids showing disorganized heads with a disruption of the cell membrane (Fig. 2G, arrowhead) and multiple flagella (Fig. 2H and I, arrow) were observed.

Ultrastructural analysis of the epididymides of 3-month-old wild-type rats showed intact cell membranes and normal-shaped heads with complete chromatin condensation of the spermatozoa (Fig. 3A1). However, the number of spermatozoa in the epididymis of transgenic rats was lower than that in wild-type rats (Fig. 3A and B). In addition, a large number of immature spermatids detaching from Sertoli cells and sloughing into the epididymides were observed (Fig. 3B1–4). Degenerated round spermatid (Fig. 3B1) and many types of abnormal elongated spermatids (Fig. 3B2–4) were frequently observed. In contrast to the normally assembled flagellar axonemes composed of nine outer doublet microtubules and a pair of central microtubules (Fig. 3A2), most spermatozoa from the transgenic rats were dead and showed various ultrastructural defects including breakage of the surface membrane (Fig. 3B5) and a decline in the number of outer dense fibers (Fig. 3B6).

**Alterations in gene expression profiles in transgenic rat testes**

cDNA microarray analysis was performed to examine alterations in gene expression evoked by HSV1-TK accumulation in transgenic rat testes. As a result, a total of two hundred genes (0.67% of all transcripts represented on the chips) had changed in expression level...
SPERMATOGENESIS DISRUPTION BY HSV1-TK

in the HSV1-TK transgenic rats in comparison with those of the wild-type rats. First, the altered genes were sorted by their functional categories including apoptosis, cell cycle, development, oxidative stress, proteolysis, signal transduction, transcription, translation, transport, immune response, metabolism and cell adhesion (Table 2). There were great numbers of affected genes in the metabolism (24 genes), transport (23 genes) and development (19 genes) categories. Of all of the altered genes, twenty-seven were upregulated and twenty-two were downregulated by at least 1.5-fold in the transgenic rat testis. We selected 10 genes (cnot7, fgf7, egfl6, testin, ostf1 and atp2a2 from upregulated genes, and sh3bp4, lame2, versican and mndc1 from downregulated genes) of interest for their roles in cell adhesion, signal transduction, transport and development (the category of each gene is listed in Table 3). To confirm the microarray data, the gene expression levels were quantified by real-time PCR. As shown in Table 3, upregulation in genes cnot7, fgf7, testin and...
ostf1 and downregulation in versican and mamdc1 were significantly consistent with the microarray data.

**Discussion**

We previously reported that the spermiogenesis of 10-week-old HSV1-TK transgenic rats is disrupted, while the processes of spermatocytogenesis and spermatidogenesis are likely to be completed [8]. The present study demonstrated the disruption of all stages of spermatogenesis predicted by histopathological alterations in 3-month-old transgenic rats. These disorders were marked in terms of seminiferous epithelial sloughing, vacuolization and degeneration in spermatocytes in addition to abnormal elongated spermatids and spermatozoa in the seminiferous lumen. cDNA microarray and real-time PCR analyses revealed that the expression levels of four genes (cnot7, fgf7, testin and ostf1) significantly increased (P<0.05) and that those of two genes (versican and mamdc1) decreased (P<0.05).

Loss of testicular function is caused by various mechanisms such as antiandrogenic effects of phthalate esters in rats [10] and fish [11], disruption of microtubule dynamics by Sertoli cell toxicants [12–16], disruption of Ca^{2+} homeostasis [17], disruption of the blood-testis barrier via the mitogen-activated protein kinase signaling pathway.
by cadmium [18], and induction of germ cell apoptosis via the Fas/Fasl signaling pathway [19]. Mono-(2-ethylhexyl) phthalate (MEHP) is known as a Sertoli cell toxicant. Giammona et al. reported that germ cell-associated death receptors, Fas and TRAIL-R2 (DR5), which participate in the regulation of germ cell apoptosis, appear to be responsive to MEHP-induced Sertoli cell injury [20]. Hild et al. administered indenopyridine CDB-4022 (a nonsteroidal male oral contraceptive) to normal rats and demonstrated that this contraceptive disrupts spermatogenesis by inducing apoptosis in early-stage germ cells via direct action on the Sertoli cells [21]. In these cases described above, histopathological changes caused by disruption of spermatogenesis are marked in terms of seminiferous epithelial sloughing, vacuolization, germ cell apoptosis and germ cell loss in the seminiferous tubules as shown in this study and our previous reports [7, 8].

Masuda et al. [22] reported ultrastructural studies on cytotoxic effects of cyclosporine A in spermiogenesis in rats exhibiting degener- ating ground spermatids, abnormal spermatozoa and residual bodies containing numerous flagella in the epidymal lumen as shown in the present study. They speculated regarding direct impairments to spermiogenic cell development and indirect effects on Sertoli cell functions including reduction of phagocytic activity by cyclosporine A. These findings described above findings suggested that the morphological alterations observed are common in testes containing injured germ cells and Sertoli cells, indicating that disruption of spermatogenesis is caused by destruction of Sertoli-germ cell adhesions. In the current study, cDNA microarray analysis was performed to better understand the underlying molecular mechanisms of HSV1-TK proteins that interfere with spermatogenesis. From 200 genes affected by the HSV1-TK, we selected 10 genes and subjected them to quantitative real-time PCR to confirm the microarray data. The results revealed that the cell adhesion-associated genes, testin, versican, and mamdc1, were significantly altered in their expression levels (P < 0.05) in the transgenic rat testes. Testin protein is considered to be a signaling molecule for monitoring Sertoli-germ cell adherens junctions (AJs), and the increased secretion of testin by Sertoli cells is in response to the disruption of Sertoli-germ cell AJs [23, 24]. The expression of versican was detected in the adult mouse brain, heart, lung, spleen, skeletal muscle, skin, tail, kidney and testis. Versican reportedly may play a role in cellular attachment, migration and proliferation by interacting with cell surfaces and extracellular matrix molecules [25]. The mamdc1 gene is expressed in human Leydig cells of the testis. Mamdc1 mRNA was upregulated by pro-inflammatory cytokines such as TNF-α and IFN-γ [26]. Mamdc1 appears to be a novel member of the adhesion molecules of the immunoglobulin superfamily (IgCAM), which is involved in cell adhesion, migration and recruitment to inflammatory sites [26]. The function of versican and mamdc1 proteins in spermatogenesis is yet obscure. On the other hand, the increased expression of growth factors, such as growth factor fgf7, osteoelast stimulating factor ostf1 and cell proliferation factor cnot7 [27], may be a stress response in the transgenic rat testes. Among these results, our focus was on testin, which is localized near the Sertoli cell surface in the testes where Sertoli and germ cells interact [28, 29].

Recently, the mechanisms of male infertility targeted by adjuvin, a contraceptive that displays the same morphogenic alterations in the seminiferous tubules as described above, have reportedly caused disruption of Sertoli-germ cell AJs by targeting directly testin protein and actin-myosin [30]. Our results showing that the expression level of testin gene increases in 3-month-old transgenic rats suggested that disruption of Sertoli-germ cell AJs occurred and triggered the derangement of spermatogenesis. Taking the findings and results of previous studies together with those of the present study including histopathological observations and microarray analysis, it is suggested that the accumulation of HSV1-TK in the spermatids first affects spermiogenesis and later disrupts all stages of spermatogenesis through an impairment of Sertoli-germ cell AJs resulting in apoptotic germ cell loss. However, the roles of HSV1-TK in these phenomena must be clarified in the near future.

It is worth noting that an accumulation of evidence has dem-onstrated that HSV infection in humans has a negative effect on male reproduction [31–35]. HSV infection, a type of sexually transmitted disease caused by HSV-1 and HSV-2, results in low sperm counts, poor sperm motility, spontaneous abortions and failure

of artificial insemination [33, 35]. In their morphology, spermatozoa showed micro-heads, cytoplasm drops on the neck [34] and possible apoptotic spermatogenic cells [36]. Previous studies in HSV-1-TK transgenic animals have demonstrated that the spermatid-specific ectopic expression of the HSV-1-TK gene in the testes oisfermangenic animais controlled under the testicular cryptic promoter within the HSV-1-TK gene [5, 8]. Therefore, we have hypothesized that the HSV-1-TK gene might be expressed in the testes of HSV-infected humans and cause male infertility. Clarification of the target of HSV-1-TK protein in transgenic animals and exploration of whether the HSV-1-TK gene is expressed in HSV-infected patients could be worthwhile and important for a better understanding of the correlation between HSV-1-TK function and male infertility.

In summary, we here provide evidence for morphological changes associated with a disruption of Sertoli-germ cell AJs and alterations in gene expression occurring in HSV-1-TK transgenic rats. We propose that the accumulation of HSV-1-TK proteins in postmeiotic spermatids interferes with not only spermiogenesis but also all processes of spermatogenesis through disruption of Sertoli-germ cell AJs. Further studies are warranted to explore the action of HSV-1-TK protein in testicular cells and its link to HSV-infected male infertility in humans.
