Abstract

Interferon tau (IFN-τ) is a ruminant-specific type I IFN secreted by a conceptus before its attachment to the uterus. IFN-τ induces the expression of IFN-stimulated genes (ISGs) via the type I IFN receptor (IFNAR), which is composed of IFNAR1 and IFNAR2 subunits in the endometrium. However, expression patterns of IFNARs during the estrous cycle have not been reported. We hypothesized that the response to a type I IFN changes along with IFNARs and the IFN-regulatory factors (IRFs) driving transcription of IFN signal-related genes and modulating a type I IFN signal during the estrous cycle. We investigated the estrous cycle stage-dependent type I IFN induction of ISGs and expression patterns of IFN signal-related genes in bovine endometrial tissues. Endometrial tissue pieces collected from bovine uteri at each estrous stage (early, mid, and late) were cultured with or without recombinant bovine IFN-α or concentrated pregnant uterine flushing (PUF) on day 18 after confirming the presence of a conceptus. IFN-α and PUF each significantly increased the expression of ISGs in endometrial tissues. The induction levels of the typical ISGs (MX1-α and ISG15) were significantly higher at the mid stage and correlated with high expression of IRFs at the mid stage. The immunostaining of IFNARs showed strong fluorescence intensities in luminal and glandular epithelia at the early and mid stages. Collectively, these results suggest that the endometrium exhibits estrous cycle stage-dependent responsiveness to type I IFN that may be associated with the expression of IFNARs and IRFs for pregnancy recognition.

Key words: Cow, IFNAR, ISG, Type I IFN, Uterus
Interferon tau (IFN-τ) is secreted by the conceptus of ruminants at the preimplantation stage [1-4]. IFN-τ is essential for pregnancy recognition in order to maintain the corpus luteum (CL). The CL is necessary for continuous production of progesterone during pregnancy. In the estrous cycle, the CL regresses, and this is followed by the next follicular phase because the CL secretes oxytocin, which binds to the oxytocin receptor expressed in the uterus and induces the CL regression factor: prostaglandin (PG) F2α [4, 5]. On the other hand, in the presence of a conceptus in the uterus, IFN-τ secreted by the conceptus inhibits the expression of oxytocin receptors. The synthesis of PGF2α is consequently inhibited, which prevents regression of the CL [4, 6]. Interferon-stimulated genes (ISGs) are strongly expressed in the uterus at this time [7-9]. Because the production of IFN-τ is limited to days 14–21 of pregnancy in cows [10], the expression of bovine Myxovirus resistance (MX) genes, typical ISGs, decreases immediately after implantation is completed, on days 25–40 [11].

The expression of ISGs is induced by the ISGF3 complex, which consists of phosphorylated and dimerized signal transducer and activator of transcription (STAT) 1/2 and IFN-regulatory factor (IRF) 9 in the IFN-stimulated Janus kinase (JAK)-STAT signaling pathway [12-14]. IFN-τ belongs to the type I IFN family, which includes IFN-α and -β, binds to type I IFN receptors (IFNARs) composed of IFNAR1 and IFNAR2 subunits [15], and subsequently activates the JAK/STAT signaling pathway [16, 17]. IFNAR1 and IFNAR2 mRNAs and proteins are strongly expressed in the endometrial luminal epithelium (LE), glandular epithelium (GE), and stromal cells in pregnant and nonpregnant ovine uteri [18]. However, only limited information is available on the expression of IFNAR in the bovine uterus. COP9 signalosome subunit 5 (COPS5)/Jun activation domain-binding protein 1—from a part of the COP9 signalosome complex that consists of eight subunits and plays a role in the ubiquitin proteasome system—was recently found to play...
a role in the inhibition of IFNAR1 proteolysis in human cells [19]. The data related to COPS5 in the bovine uterus have not been reported.

Type I IFN is generally induced by viral infections, and ISGs show antiviral activity [20]. The transcription of some type I IFNs—IFN-α and -β—is regulated by IRF3 and -7 [13, 14]. On the other hand, the transcription of IFN-τ is regulated by other transcription factors such as ETS2 [21], AP1 [22], CDX2 [23], DLX3 [24], and GATA2 [25]. IFN-τ and IFN-α differ in the transcription-regulatory mechanism even though they are both type I IFNs. The luteotropic activities of IFN-α and IFN-τ have been explored in previous studies. Intrauterine and intramuscular administration of recombinant bovine IFN-α to cows has been shown to reduce the oxytocin-induced release of PGF2α and to extend the lifespan of the CL [26-28]. Similarly, infusion of recombinant ovine IFN-τ or IFN-α to ewes extends the estrous cycle [29]. In vitro, recombinant bovine IFN-τ and IFN-α, recombinant ovine IFN-τ, and human IFN-α have been shown to suppress the synthesis of PGF2α in bovine and ovine endometrial cells [30, 31]. Thus, IFN-α and IFN-τ have antiluteolytic activities. A comparative analysis of gene expression profiles in the bovine endometrium between early pregnancy (days 15 and 18) and the intrauterine application of human IFN-α revealed similar and differential gene expression patterns, suggesting that IFN-τ-specific gene induction takes place in the endometrium at the preimplantation stage in the uterus [32]. The typical ISGs—MX1, MX2, and ISG15—are expressed in early pregnancy and after application of IFN-α and show similar gene expression patterns. It currently remains unknown whether IFN-τ-induced ISGs play roles in immune responses or have pregnancy recognition-specific functions in the uterus at the preimplantation stage.

Only ruminant-specific IFN-τ has antiluteolytic activities for pregnancy recognition between the mother and embryo [33]. However, not having antiluteolytic activities, other type I IFN such as porcine and equine IFN-δ or human and murine IFN-ε are expressed in the endometrium and
trophoblast cells [34-37] and have been suggested to play roles in achieving a successful pregnancy. Additionally, the expression of genes IFNAR1, IFNAR2, and MxA shows similar changes in the endometrium during the menstrual cycle in humans [38]. We hypothesized that the estrous cycle stage-dependent responsiveness to type I IFN in the bovine endometrium is accompanied by a change in the expression of IFNARs and IRFs. In the present study, we investigated type I IFN-mediated induction of ISGs and expression patterns of IFN signal-related genes in bovine endometrial tissue at each estrous stage: early, mid, and late.

Materials and Methods

Collection of samples of endometrial tissues

This study was conducted in accordance with the Hokkaido University guidelines for the care and use of animals. Uteri collected from abattoirs were subdivided into three stages; early (days 4–9), mid (days 10–15), and late (days 16–21) according to the luteal stages of the ovary [39] as well as the status and electrical impedance of uterine mucus [40]. Intercaruncular endometrial tissues were collected from the uterine horn ipsilateral to the CL. The collected tissues were embedded in Optimal Cutting Temperature compound (Sakura Finetek Co., Ltd., Tokyo, Japan) in liquid nitrogen, and stored in a freezer at -80°C until section preparation. Moreover, the collected tissues were used in expression analyses or explant cultures. Noncultured tissue samples were stored in a freezer at -80°C until RNA extraction. All the experiments were conducted on the tissue samples of at least three cows at each stage.

Uterine flushing and bovine recombinant IFN-α

Pregnant uterine flushing (PUF) was collected from a cow, confirming the existence of a conceptus on day 18 of pregnancy after embryo transfer on day 7 of the estrous cycle.
Nonpregnant uterine flushing (NPUF) was collected from a cow confirmed to not have a conceptus after embryo transfer on day 7 of the estrous cycle. Approximately 2 l of each collected uterine flushing was filtered through gauze to remove cell debris. Then, the flushing was concentrated to 20 ml by means of a dialysis membrane (Size 36, Wako, Osaka, Japan) and dehydrated using polyethylene glycol 20,000 (Merck Schuchardt OHG, Hohenbrunn, Germany) at 4°C overnight. Concentrated uterine flushing was finally filtered through a 0.45-μm membrane, and then stored in a freezer at -80°C. Bovine recombinant IFN-α was kindly provided by Novartis (Novartis Animal Health Inc., Basel, Switzerland).

The IFN-τ protein was detected in PUF by a western blot analysis. The antiviral activities of PUF and IFN-α were measured by a viral resistance assay using Madin-Darby bovine kidney cells and were found to be 82,620 IU/ml and 602,290 IU/ml, respectively. Five microliters of PUF or 0.5 μl of IFN-α was added to 1 ml of the medium, which was adjusted to approximately 400 IU/ml or 300 IU/ml. Five microliters of NPUF (the volume equivalent to that of PUF, 5 μl) was also added to the medium as a negative control.

Explant culture conditions

Collected tissues were placed in calcium- and magnesium-free Hanks’ balanced salt solution (HBSS) (-) and cut into small pieces (5 x 5 mm). These pieces were preincubated in Dulbecco’s Modified Eagle’s medium – high glucose (DMEM, Sigma-Aldrich, St. Louis, MO, USA) supplemented with 0.06 g/l penicillin G potassium (Nacalai Tesque, Inc., Kyoto, Japan) and 0.1 g/l streptomycin sulfate (Nacalai Tesque) at 38.5°C [41, 42] for 1 h at 5% of CO₂. The medium volume was 2 ml in Falcon 35-mm Easy Grip Style Not Treated Bacteriological Petri Dishes, Sterile (Becton, Dickinson and Company, Franklin Lakes, NJ, USA). After the preincubation, endometrial tissue pieces were cultured with nonsupplemented DMEM containing 10% (v/v) of
fetal bovine serum (FBS, ICN Bio-Source International, Camarillo, CA, USA) (Cont.) or DMEM
containing 10% of FBS and supplemented with IFN-α (300 IU/ml), PUF (400 IU/ml), or NPUF
(5 μl/ml) for 12 or 24 h at 38.5°C and 5% CO₂ in duplicate. The medium volume was 0.5 ml/well
in Thermo Scientific™ Nunc™ Cell-Culture Treated Multidishes with 24 round wells (Thermo
Fisher Scientific, Roskilde, Denmark). Cultured tissues were stored in a freezer at -80°C until
RNA extraction.

RNA extraction and quantitative reverse-transcription polymerase chain reaction (qRT-PCR)

Total RNA was extracted from tissues homogenized using BioMasher® (Nippi, Tokyo, Japan)
by NucleoSpin® RNA II (MACHERY-NAGEL, Düren, Germany) according to the
manufacturer’s protocol. All RNA samples were stored in a freezer at -80°C. Each RNA sample’s
concentration was measured by spectrophotometry (NanoDrop ND-2000, Thermo Scientific,
Wilmington, DE, USA), and cDNA was synthesized from 0.2 μg of total RNA by reverse
transcription using the ReverTra Ace® qPCR RT Master Mix (Toyobo Life Science, Osaka, Japan)
according to the manufacturer’s protocol. PCR was run on an Astec Program Temp Control
System (PC-815 or 816, Astec, Fukuoka, Japan). All cDNA samples were stored in a freezer at -
30°C. Specific primers for MX1-a, MX1B, MX2, ISG15, IDO1, IFNAR2, COPS5, IRF1, IRF2,
IRF3, IRF9, and H2AFZ were designed using Primer-BLAST
(http://www.ncbi.nlm.nih.gov/tools/primer-blast/). Primer details are shown in Table 1. The
relative expression levels of MX1-a, MX1B, MX2, ISG15, IFNAR1, IFNAR2, COPS5, IRF1, IRF2,
IRF3, and IRF9 were assessed by qRT-PCR using a LightCycler® 480 System II (Roche
Diagnostics, Basel, Switzerland) and THUNDERBIRD™ SYBR® qPCR Mix (Toyobo Life
Science) added at the final concentration of each primer 0.5 μM. Thermal cycling conditions were
1 cycle at 95°C for 30 sec (denaturation), followed by 50 cycles at 95°C for 10 sec (denaturation),
55°C for 15 sec (primer annealing), and 72°C for 30 sec (extension). Relative mRNA abundance was calculated by the ΔΔCt method using the expression of H2AFZ as a reference gene.

Immunohistochemical analysis of frozen tissue slices

Frozen tissue slices were prepared and mounted on slides (Kenis, Osaka, Japan) using a Leica CM3050 S Research Cryostat (Leica Biosystems, Nussloch, Germany) and fixed in 4% (w/v) paraformaldehyde in calcium- and magnesium-free phosphate-buffered saline (PBS) (-) for 15 min. The samples were then washed three times with PBS (-) for 5 min and permeabilized by incubation with PBS (-) containing 0.2% (v/v) Triton X-100 (PBS-T) for 10 min. After three washes with PBS (-) for 5 min, the samples were blocked with 1% (w/v) BSA (Sigma) in PBS-T for 1 h. After three washes with PBS (-) for 5 min, the samples were incubated with a primary rabbit polyclonal antibody to IFNAR1 (sc-845, Santa Cruz Biotechnology, Inc., Dallas, TX, USA) or IFNAR2 (GTX105770, GeneTex, Inc., CA, USA) diluted 1:500 with Solution A of Can Get Signal Immunostain Immunoreaction Enhance (Toyobo Life Science) at 4°C overnight. The samples were washed three times with PBS (-) for 5 min, and incubated for 1 h with a fluorescein-conjugated secondary antibody (Alexa Fluor® 568-conjugated donkey anti-rabbit IgG antibody, A10042, Thermo Fisher Scientific, CA, USA) diluted 1:200 with Solution A of Can Get Signal Immunostain Immunoreaction Enhance (Toyobo Life Science). The samples were washed three times with PBS (-) for 5 min, covered with 10 μl of the mounting solution, Vectashield with DAPI (Vector Laboratories, Burlingame, CA, USA), and examined under a confocal microscope (Leica TCS SP5 II, Leica Biosystems).

Statistical analysis

All data are shown as the mean ± standard error of the mean (SEM). The significance of
differences was assessed by analysis of variance (ANOVA) followed by Fisher’s protected least-
significant difference (PLSD) procedure as a multiple-comparison test in the StatView statistical
analysis software (version 5; SAS Institute Inc., Cary, NC, USA). Data with P values of < 0.05
were considered significant. P values of < 0.1 were assumed to indicate a slight difference.

Results

Induction of ISG mRNAs in mid-stage endometrial tissues cultured with IFN-α or PUF

PUF stimulated the expression of ISGs as well as IFN-α did. The expression of MX1-a and
ISG15 significantly increased in tissues cultured for 12 and 24 h with IFN-α or PUF (Fig. 1 A and
D; P < 0.05). The expression of MX2 significantly increased in tissues cultured for 12 and 24 h
with IFN-α or for 12 h with PUF (Fig. 1 C; P < 0.05). The expression of MX1B significantly
increased in tissues cultured for 12 h with IFN-α or PUF (Fig. 1 B; P < 0.05). The expression of
all ISGs was sufficiently induced in tissues cultured for 12 h with IFN-α or PUF, not with NPUF
for 12 or 24 h.

Expression of ISG mRNAs stimulated by IFN-α or PUF in endometrial tissues at each stage

In tissues cultured for 12 h, the magnitude of induction of MX1-a by PUF was significantly
greater at the mid stage than at the early and late stages (Fig. 2 A; P < 0.05). Additionally, the
induction of MX1B by PUF and ISG15 by IFN-α or PUF was significantly stronger at the mid
stage than at the late stage (Fig. 2 B and D; P < 0.05). In spite of the absence of a significant
difference, the expression of MX1-a under the influence of IFN-α from the mid to late stage and
MX1B under the influence of PUF from the mid to early stage had a tendency to be high (Fig. 2
A; P = 0.079, B; P = 0.085). No significant difference was observed in the expression of MX2
among tissues of all stages cultured for 12 h with IFN-α or PUF.
Changes in the expression of IFNAR1, IFNAR2, COPS5, IRF1, IRF2, IRF3, and IRF9 mRNAs during the estrous cycle

In noncultured tissues, IFNAR1, IFNAR2, and COPS5 mRNAs were strongly expressed at the early stage. The expression of IFNAR1 mRNA was slightly stronger at the early stage than at the mid stage (Fig. 3 A; \( P = 0.057 \)). The expression of IFNAR2 mRNA was significantly stronger at the early stage than at the other stages (Fig. 3 B; \( P < 0.05 \)). The expression of COPS5 mRNA was slightly stronger at the early stage than at the late stage (Fig. 3 C; \( P = 0.093 \)). IRF1, IRF2, IRF3, and IRF9 mRNAs were strongly expressed at the mid stage. The expression of IRF1 and IRF2 mRNAs was slightly stronger at the mid stage than at the early stage (Fig. 3 D and E; \( P = 0.065 \) and 0.055). The expression of IRF2 and IRF3 mRNAs was significantly stronger at the mid stage than at the late stage (Fig. 3 E and F; \( P < 0.05 \)). The expression of IRF9 mRNA was significantly stronger at the mid stage than at the early and late stages (Fig. 3 G; \( P < 0.05 \)).

Expression and localization of IFNAR1 and IFNAR2 proteins in endometrial tissues at each stage

IFNAR1 and IFNAR2 proteins were detected in the LE and GE in each tissue slice (Fig. 4 A and Fig. 5 A). The fluorescence intensities of IFNAR1 and IFNAR2 were strong at the early and mid stages and weak at the late stage. The localization of IFNAR1 in GE was clearer at the mid stage. The relative fluorescence intensities of IFNAR1 in LE and GE significantly decreased from the early to late stage (Fig. 4 B and Fig. 5 B; \( P < 0.05 \)), whereas those of IFNAR2 in LE and GE remained stable from the early to mid stage and were slightly weaker at the late stage (Fig. 4 C and Fig. 5 C; \( P < 0.05 \) and \( P = 0.087 \)).

Discussion
The present study demonstrated that the type I IFN response is strong at the mid stage of the
estrous cycle according to the induction levels of ISG mRNAs in endometrial tissues cultured
with a type I IFN. Additionally, this result was associated with the expression of IFNARs and
IRFs in the endometrium. These data suggest that the endometrium at the mid stage of the estrous
cycle requires specific conditions to respond to IFN-τ for pregnancy recognition between a mother
and fetus in cows.

In other studies, IFN-τ has been detected in the PUF of cows, whereas other type I IFNs were
not [43, 44]. Sakurai et al. [45] applied PUF as an alternative to IFN-τ and reported promotion of
the processes of attachment of bovine trophoblast cells to endometrial epithelial cells, thereby
mimicking the uterine environment at the peri-implantation stage in vivo. In the present study, the
bovine endometrial reaction to a type I IFN was investigated by the experimental method of an
explant culture with the PUF.

We initially attempted the explant culture at IFN-α concentrations of 300 IU/ml and 3000 IU/ml
at the mid stage (when pregnancy recognition occurs), as reported previously for a bovine embryo
culture [46], and evaluated the relative expression of ISGs (MX1-a and MX1B) in cultured tissues.
Both concentrations similarly induced MX1-a and MX1B mRNA expression (Supplemental Fig.
1). These results indicate the absence of significant differences in type I IFN induction levels
within an antiviral activity range between 300 IU/ml and 3000 IU/ml. PUF and IFN-α both
sufficiently stimulated the expression of ISGs in the tissues cultured for 12 h (Fig. 1). Accordingly,
we compared the expression of ISGs in tissues cultured for 12 h with PUF or IFN-α at each stage:
the early, mid, and late stages.

In tissues cultured with PUF or IFN-α, the expression of MX1-a, MX1B, and ISG15 was high
at the mid stage (Fig. 2 A, B, and D). MX and ISG genes have been shown to suppress viral
proliferation in the innate immune system [14, 47, 48]. When progesterone is dominantly
produced in livestock, the suppression of immune functions in the uterus enhances the risk of uterine infection [49]. In humans, progesterone was found to suppress IFN-α-induced MxA expression in peripheral blood mononuclear cells infected with hepatitis C virus [50]. ISGs may prevent infection at the preimplantation stage.

The expression of IFNAR1 and IFNAR2 mRNAs was strong at the early stage (Fig. 3 A and B). A small amount of IFN-τ is known to be produced in vitro by hatched blastocysts (days 8–10) [51]. IFN-τ-mediated signal transduction prior to the peak in IFN-τ production may be necessary for achieving a successful pregnancy. The results of the immunohistochemical analysis showed strong fluorescence intensities of IFNAR1 and IFNAR2 from the early to mid stage and their weak intensities at the late stage (Fig. 4 and 5). Furthermore, the IFNAR1 protein was clearly localized to the cytoplasm or cell membrane in GE at the mid stage; therefore, the IFNAR1 protein may be more functional at the mid stage. In addition, the expression of COPS5 decreased slightly from the early to late stage (Fig. 3 C). COPS5 has been shown to stabilize IFNAR1 protein levels by regulating ubiquitination and degradation [19]. These findings suggest that IFNAR is strongly expressed at the early stage because the uterus needs to prepare to respond to IFN-τ for pregnancy recognition at the mid stage. On the other hand, in the absence of a conceptus, the IFNAR protein is degraded from the mid to late stage.

All IRF genes were strongly expressed at the mid stage (Fig. 3 D–G). IRF1 regulates DNA damage and apoptosis in addition to activating immune responses including type I IFN signaling [13, 52]. One study suggested that IFN-τ induces apoptosis in bovine endometrial cells [53]. IRF1 activates the induction of IFN-τ-stimulated genes and may regulate the apoptosis in the endometrium for uterine tissue remodeling at the peri-implantation stage. IRF2 has been shown to inhibit the type I IFN signaling pathway [13, 54]. It may also suppress excessive responses to a type I IFN in the endometrium because a successful pregnancy requires immune tolerance. IRF3
is a transcriptional regulator of IFN-α and -β in the innate immune system [13, 14]. This observation suggests that not only the production of IFN-τ but also the expression of type I IFNs such as IFN-α and -β in maternal uterine tissues is necessary for pregnancy recognition. IRF9 drives the transcription of ISGs [13, 14]. The strong expression of IRF9 at the mid stage may enable endometrial tissues to positively respond to IFN-τ, and consequently, the expression of MX1-a, MX1B, and ISG15 is strong at the mid stage. As described above, IRF genes may be involved in the type I IFN response for pregnancy recognition; in particular, the expression of IRF1 and IRF9 is more important than that of IFNAR because they serve as the activator and transcription factor in type I IFN signaling after binding of IFN-τ to IFNAR.

In conclusion, herein we demonstrated that the endometrium responds to a type I IFN specifically at the mid stage of the estrous cycle. To the best of our knowledge, this is the first study to examine stage-dependent differences in the induction of ISGs by a type I IFN in bovine endometrial tissue. The expression of IFNARs and IRFs is key to the type I IFN response in the bovine endometrium during the estrous cycle. These results suggest that the bovine endometrium prepares for pregnancy recognition via IFN-τ and easily responds to IFN-τ at the mid stage. ISGs induced by IFN-τ may play important roles in the endometrium for successful implantation, for example, protection from viral and other infections.

Acknowledgments

This study was supported by a Grant-in-Aid for Scientific Research from the Japan Society for the Promotion of Science (KAKENHI, 15H04579) and partially by the Cooperative Research Program for Agriculture Science & Technology Development (RDA, PJ01029304).
