Effects of Gas Inertia Forces on Dynamic Characteristics of Externally Pressurized Gas-Lubricated Thrust Bearings* (Evaluation of Various Approximate Solutions Under Highly Unsteady Conditions)

Yoshio HARUYAMA**, Atsunobu MORI***, Haruo MORI***, Fusao MIKAMI** and Hiroki AIKAWA****

In this report, the modified averaging approach to the solution for the dynamic performance of an externally pressurized, gas-lubricated, circular thrust bearing in a laminar flow regime, is presented under the assumption of a small harmonic vibration. This approach can evaluate the inertia effects under highly unsteady conditions. The accuracy of the approximate solutions presented in a previous report are compared and evaluated under similar conditions and the following conclusions are obtained:

1. The conventional averaging approach, in which all the inertia terms are averaged out across the film thickness, gives a good approximation.
2. The first-order solution of the perturbation method becomes remarkably inaccurate as the unsteadiness becomes high.

**Key Words**: Lubrication, Theoretical Analysis, Externally Pressurized Gas Bearing, Inertia Effect, New Approximate Analysis, Dynamic Performance

1. Introduction

In a previous report†, analytical models were introduced to predict the effects of the inertia forces of a gas film flow on the dynamic properties of an externally pressurized, gas-lubricated, circular thrust bearing with a single central supply hole. Those models enabled the analysis of the dynamic performance of such a bearing over a wide range of design conditions. The calculated results may, however, become inaccurate as the unsteadiness becomes high. In other previous reports‡, the modified averaging approach was introduced for the dynamic performance of an externally pressurized thrust bearing lubricated with an incompressible fluid, and it was found that this approach yield good results under highly unsteady conditions because of the exact treatment of the local acceleration terms in the momentum equation. In this report, the dynamic performance of an externally pressurized gas-lubricated circular thrust bearing is analyzed by means of such a modified averaging approach. The previous approximate solutions§ are compared with this to evaluate their accuracy under highly unsteady conditions.

2. Governing Equations and Boundary Conditions

Figure 1 shows schematically the externally pressurized circular thrust, gas bearing with a single central supply hole of inherent compensation. This bearing, subjects to analysis, has a uniform film thickness without any recess. The gas, with a constant pressure $p_0$, is fed into the central hole. The flow is assumed to be laminar and isothermal. With these assumptions and the usual assumptions of gas-film lubrication theory, the momentum equations, the continuity equation and the equation of state are given as follows:

$$\rho \left( \frac{\partial u}{\partial t} + u \frac{\partial u}{\partial r} + w \frac{\partial u}{\partial z} \right) = -\frac{\partial p}{\partial r} + \mu \frac{\partial^2 u}{\partial z^2}$$  (1)

JSME International Journal

\begin{align}
0 &= \frac{\partial p}{\partial z} \\
\frac{\partial p}{\partial t} + \frac{1}{r} \frac{\partial}{\partial r} (rp_\omega) + \frac{\partial}{\partial z} (p\omega) &= 0 \\
\rho \frac{\partial}{\partial t} &= \mathcal{R} T_0
\end{align}

where \( u \) and \( w \) are the velocity components in the \( r \) and \( z \) directions, \( p \) is the pressure, \( \rho \) is the density, \( t \) is the time, \( \mathcal{R} \) is the gas constant, and \( T_0 \) is the temperature of the bearing. The boundary conditions are

\[
\begin{aligned}
z = 0 &: u = w = 0 \\
z = h &: u = 0, \quad w = \frac{dh}{dt} \\
r = r_0 &: \rho = \rho_a \\
r = r_s &: \rho = \rho_i
\end{aligned}
\]

where \( \rho_a \) is the ambient pressure and \( \rho_i \) is the pressure at the feeding section which is determined by the continuity condition of mass flow rate.

It is difficult to obtain exact solutions to the above governing equations. Therefore, various approximate solutions have been introduced. In the next chapter, assuming a small harmonic vibration, we will formulate the modified averaging approach, in which the local acceleration terms in the momentum equation are treated as exactly as possible.

3. Modified Averaging Approach

To apply the modified averaging approach to this problem, it should be premised that the flow is unchoked at the inlet to the clearance space, because this approach cannot be formulated for a choked condition. Since the velocity and the pressure can be divided into two-components of the quasi-statical (subscript \( q \)) and the dynamical (subscript \( t \)) ones, we can write them as

\[
(u, w, \rho) = (u_q, w_q, \rho_q) + (u_t, w_t, \rho_t)
\]

Assuming a small harmonic variation in the film thickness,

\[
h = h_0 + h_1 e^{j\omega t}
\]

Corresponded to this expression, the dynamical components of velocity and pressure are given:

\[
\begin{aligned}
(u_t, w_t, \rho_t) &= (\tilde{u}_t, \tilde{w}_t, \tilde{\rho}_t) e^{j\omega t} \\
(u_q, w_q, \rho_q) &= (u_t, w_t, \rho_t)
\end{aligned}
\]

(8)

Substituting Eqs. (6) through (8) into Eqs. (1) through (5), we can formulate the following governing differential equations and boundary conditions:

Quasi-statical components

\[
\begin{aligned}
\frac{p_q}{\mathcal{R} T_0} \left( u_q \frac{\partial u_q}{\partial r} + w_q \frac{\partial u_q}{\partial z} \right) &= - \frac{\partial p_q}{\partial r} + \frac{\partial}{\partial z} \left( \frac{\partial u_q}{\partial z} + \frac{\partial}{\partial z} \left( p_a w_i \right) \right) \\
\frac{1}{r} \frac{\partial}{\partial r} (r p_q w_i) &= 0
\end{aligned}
\]

Boundary conditions

\[
\begin{aligned}
z = 0 &: u = w = 0 \\
r = r_0 &: p = p_a \\
r = r_s &: p = p_i
\end{aligned}
\]

Dynamical components

\[
\begin{aligned}
\frac{p_t}{\mathcal{R} T_0} \left( j \omega h_1 \frac{\partial u_q}{\partial h} + j \omega w_i + u_q \frac{\partial \tilde{u}_t}{\partial r} + \frac{\partial \tilde{w}_t}{\partial z} \right) + \frac{\tilde{p}_t}{\mathcal{R} T_0} &+ \frac{\partial}{\partial z} \left( \frac{\partial u_q}{\partial z} + \frac{\partial}{\partial z} \left( p_a w_i \right) \right) \\
&= - \frac{\partial \tilde{p}_t}{\partial r} + \frac{\partial}{\partial z} \left( \frac{\partial \tilde{u}_t}{\partial z} \right)
\end{aligned}
\]

Boundary conditions

\[
\begin{aligned}
z = 0 &: \tilde{u}_t = \tilde{w}_t = 0 \\
z = h_0 &: \tilde{u}_t = 0, \quad \tilde{w}_t = j \omega h_1 \\
r = r_0 &: \tilde{p}_t = 0 \\
r = r_s &: \tilde{p}_t = \tilde{p}_i
\end{aligned}
\]

where \( j = \sqrt{-1} \) and \( \omega \) is the angular frequency of the squeeze motion. From Eq. (7), it should be noted that the real parts of the complex quantities in the solutions, \( u_t, w_t, \) and \( \rho_t \), have physical meaning. Since it is difficult to obtain exact solutions of the above governing equations, we use the averaging approach, in which the inertia terms, except the term of \( j \omega \rho_0 \tilde{u}_t / (\mathcal{R} T_0) \), are averaged out across the film thickness. \( f_\tau \) and \( f_\rho \) are defined as:

\[
\begin{aligned}
f_\tau &= \frac{1}{\mu} \frac{\partial p_a}{\partial r} + \frac{p_a}{\mu \mathcal{R} T_0 h_0} \left( \int u_q \frac{\partial u_q}{\partial r} + w_i \frac{\partial u_q}{\partial z} \right) \\
\end{aligned}
\]

\[
+j \omega \tilde{w}_t \frac{\partial \tilde{u}_t}{\partial z} \right) dz
\]

\[
\text{Fig. 1 Schematic view of externally pressurized thrust bearing with a single central supply hole}
\]
\[
\begin{align*}
\dot{f}_1 &= \frac{1}{\mu} \frac{\partial \varphi}{\partial r} + \frac{1}{\mu R T_0 h_0} \int_0^M p_0 \left( j \omega \frac{\partial u_x}{\partial t} \right) dz \left( \frac{1}{\mu R T_0 h_0} - u_x \frac{\partial u_x}{\partial r} + \frac{u_x \partial u_x}{\partial r} + u_y \frac{\partial u_x}{\partial z} + u_z \frac{\partial u_x}{\partial z} \right) + \varphi_1 \left( \frac{u_x \partial u_x}{\partial r} + u_x \frac{\partial u_x}{\partial z} \right) dz, \\
&= \frac{1}{\mu R T_0 h_0} \int_0^M p_0 \left( j \omega \frac{\partial u_x}{\partial t} \right) dz.
\end{align*}
\]

The velocity components are obtained as follows:

\[
\begin{align*}
u_z &= \frac{f_z}{\varphi} z (z - h) \quad (20) \\
u_x &= \frac{1}{12 \rho_p} \frac{d}{dr} \left( \rho_p \varphi \right) z^2 (z - 3h) \quad (21) \\
\varpi &= \frac{1}{\rho_p} \frac{1}{4 \eta} \left( - j \omega \frac{h \partial p}{\partial h} \partial h + \hat{p} \right) \quad (22) \\
\end{align*}
\]

With the boundary conditions of Eqs.(13) and (17), Eqs.(21) and (23) result in:

\[
\begin{align*}
\frac{\partial}{\partial r} \left( \varphi \partial r \right) &= 0 \quad (24) \\
1 - \left[ \frac{\partial}{\partial r} \left( \frac{\partial}{\partial r} \right) \right] \left( \frac{1}{\eta} \cosh(\gamma \sqrt{\rho \varphi z - z - \gamma \sqrt{\rho \varphi h_0}}) \right) &\quad (25)
\end{align*}
\]

The dimensionless coefficients are obtained through the modified averaging approach. From the following dimensionless quantities:

\[
\begin{align*}
\bar{P}_s &= \frac{p_s}{p_a}, \quad P_s = \frac{p_s}{p_a}, \\
\bar{P}_t &= \frac{P_t}{p_a}, \quad F_s = \frac{F_s}{F_a}, \\
\end{align*}
\]

we can obtain normalized forms of Eqs.(24),(25),(26) and (27) as follows:

\[
\begin{align*}
\frac{d}{dr} \left( \varphi \varphi \right) F_s &= 0 \quad (28) \\
F_s &= \frac{\partial F_s}{\partial r} \left( \frac{5}{R} \frac{d}{dr} \left( \alpha P_s F_s \right) \right) \quad (29) \\
\end{align*}
\]

where (28) through (31) are calculated numerically by means of the Runge-Kutta-Gill method.

The dimensionless dynamic stiffness (K) and the dimensionless damping coefficient (B) are defined in the same manner as those in the previous report. They are determined by the following four dimensionless designing parameters:

\[
\begin{align*}
R &= \frac{R_s}{R_0} \quad (the \ dimensionless \ radius \ of \ the \ supply \ hole) \\
P_s &= \frac{p_s}{p_a} \quad (the \ dimensionless \ supply \ pressure) \\
\end{align*}
\]

and the discharge coefficient (C_d). In the unsteadiness parameters, \( \rho_s \) is the density at the ambient pressure (\( p_a \)). The unsteadiness parameter (\( R_{\sigma}^{\alpha*} \)) represents the ratio of the local acceleration term to the viscous term. The average above parameters are related to \( \sigma, \alpha \) and \( \varphi \).
by the following equations:

\[ \sigma = \frac{1}{12} \left( \frac{\Gamma}{C_{d}R_{s} \ln R_{s}} \right)^{2} Re^{**} \]  \hspace{1cm} (33) \\
\[ a = \left( \frac{-C_{d}R_{s}}{\Gamma} \ln R_{s} \right)^{2} \]  \hspace{1cm} (34) \\
\[ \varphi = \frac{\sqrt{2Re^{**}}}{2} \]  \hspace{1cm} (35)

As mentioned already calculated results by this modified averaging approach are expected to be accurate under highly unsteady conditions because the local acceleration terms are treated exactly.

4. Comparison among Various Approximate Solutions

The approximate solutions presented in the previous paper\(^{(1)}\) are valid under the conditions of \(a \ll 1\) and \(Re^{**} \ll 1\) because they are based on rough treatment of the inertia terms including the local acceleration terms. On the other hand, the modified averaging approach is expected to be valid for any value of \(Re^{**}\). The calculated results by this approach can be accurate under highly unsteady conditions because, in this approach, the local acceleration terms in the momentum equation are treated as exactly as possible. In this chapter, the previous approximate solutions\(^{(1)}\) are compared with the calculated results by the modified averaging approach to evaluate their accuracy. This comparison is made for unchoked conditions because the modified averaging approach cannot be applied for a choked condition.

Figure 2 shows the comparison of various approximate solutions for the dimensionless dynamic stiffness \((K)\) and the dimensionless damping coefficient \((B)\). In this figure, the symbols, MAA, AA and PM indicate the results by the modified averaging approach, the averaging approach, and the first-order perturbation method, respectively. The symbols, Solution 1 and Solution 2, indicate the results by the analytical models presented in a previous report\(^{(1)}\). The broken lines (LT) show the results by the classical lubrication theory. One can find in this figure that the conventional averaging approach, in which all the inertia terms are averaged out across the film thickness, gives a good approximation even under highly unsteady conditions, and that the results of Solution 1 also give a fairly good approximation. The results of Solution 2 are inaccurate except the region of small values of \(Re^{**}\). The first-order solutions of the perturbation method become remarkably inaccurate when the value of \(Re^{**}\) is large.

5. Conclusions

The modified averaging approach to the solution for the dynamic stiffness and the damping coefficient of an externally pressurized, gas-lubricated, circular thrust bearing, was presented under the assumption of a small harmonic vibration. The previous approximate solutions was compared with the results of this approach to evaluate their accuracy under highly unsteady conditions. The following conclusions have been obtained:

1. The averaging approach gives good approximations, and solution 1 gives fairly good approximations.
2. The perturbation method becomes remarkably inaccurate when the value of \(Re^{**}\) is large.
3. Solution 2 is quite inaccurate except for small values of \(Re^{**}\).

These conclusions are obtained for an unchoked condition. Similar conclusions may be expected for a choked condition.
