Fiber Breakage in Spinning Operations

Part 1: Statistical Analysis of the Breaking Process

By Hiraku Takeda, Member, TMSJ

Based on Journal of the Textile Machinery Society of Japan, Transactions, Vol. 21, No.4, T71–80 (1968)

Abstract

Variations in the fiber length distribution caused by the breakage process, which is assumed to be steady and continuous in time, are discussed generally.

Statistically, such a process is defined by three fractions: (a) the fraction $\alpha(l) \Delta t$ that a fibre of length $l$ breaks in time $\Delta t$; (b) $\beta(l) \Delta l$ that breakage occurs in $l-\Delta l$ along a fibre axis having $l$; and (c) $\gamma(l) \Delta l$ that fibre length $l$ is lost in time $\Delta t$.

From those fractions an integro-differential equation has been derived giving the number-frequency distribution of fibre lengths at any instant. The equation is soluble by arbitrary functions.

Assuming $\gamma=0$, methods to obtain $\alpha$ and $\beta$ experimentally and the upper bound of total number at any instant have been investigated.

By applying the above results to breakage in roller carding, the following estimate of $\alpha$ and $\beta$ has been obtained:

$$\alpha(l) = k l^{2.5}$$

$$\beta(l_2 \rightarrow l) = \frac{6}{l_2^3} \left(1 - \frac{l}{l_2}\right)$$

Experimental and calculated distributions agree well if this estimate is used.

KEY WORDS: fiber length, fiber breakage, fiber length distribution, frequency distribution (fiber length), breaking.

1. Introduction

The fiber length distribution, one of the major characteristics of spinning material, is not invariable but, instead, varies continuously during spinning operations. Variations in the fiber length distribution are produced mainly two factors:

1. The elimination of short fibers through the spinning operation, e.g., waste, flyout, etc.

2. The increase in the number of short fibers due to fiber breakage during the spinning process.

Factor (2) occasionally causes to more comber noil, more end-breakage and more drafting wave. This is clearly borne out by R. Bownass report that the percent reduction of mean fiber length on a worsted card reaches 20–65%.

The fiber breakage is closely affected by the physical properties of fibers and their assemblies and by the mechanical actions of spinning process on the fiber material. In other words, the variations of shape in the fiber length distribution are strongly affected by these properties and actions. Therefore, an analysis on variations in the fiber length distribution will give an aid to clarify the mechanical actions in the spinning operation.

In addition to R. Bownass work, there are a number of works dealing with fiber breakage in spinning operations, e.g., D.A. Ross, P.P. Townend's, R. Bownass etc. They are all limited to experimental discussion on the relations between fiber breakage and the properties of materials. Byatt, et al's work seems uniquely interesting, in that it tries to find the equation to express variations in the fiber length distribution caused by fiber breakage, characterizing a breakage process by the breakage ratio and distribution of breaking points and also to solve the equation in the case of specific process, i.e., the breakage are occured proportionally to fiber length and uniformly along the fiber axis.

Journal of The Textile Machinery Society of Japan 214
Using the same concept as Byatt, et al., the present article discusses theoretically about the generalized breakage process and presents the results of applying this theory to experiments made on roller card.

2. Equation on Fiber Breakage Process

The author makes an assumption that the breakage process is continuous and steady with operating time $t$, and that the loss of fibers during operating time may be ignored. Byatt, et al.'s concept can, therefore, be used here to deduce a breakage equation, by which to express the fiber length distribution at time $t$. To facilitate the theoretical treatment of process we replace the fiber length distribution with a number-frequency distribution of fibers. The results presented in this article are convertible into a weight-frequency distribution[note], as a matter of course.

We define the functions as follows:

- $n(l,t)\Delta l$: The expected number of fibers of length $l$ to $l+\Delta l$ included in the fibers of unit weight at time $t$.
- $\alpha(l)$: The fraction of fibers of length $l$ that are broken in time $\Delta t$. Then, the reciprocal of $\alpha(l)$ means a life time.
- $\beta(l_1\rightarrow l)\Delta l$: The fraction that the breakaging points are within $l$ to $l+\Delta l$ from one end of each fiber when fibers of length $l_1$, where $l<l_1$, are broken. $\beta(l_1\rightarrow l)$ is referred to here as the “distribution of breaking points”.

Take fibers $l_1$ to $l_1+\Delta l$ in length and consider the variations in amount of such fibers, during the interval $t$ to $t+\Delta t$, produced by:

(a) The decrease of fibers of length $l$ to $l+\Delta l$ being broken into shorter fibers.
(b) The increase caused when the fibers of length $l_1$, where $l_1>l+\Delta l$, are broken into the fibers of length $l$ to $l+\Delta l$.

It is easy to see how the preceding item (a) takes the form of $-\alpha(l)n(l,t)\Delta l$. As for item (b), since the number of fibers of $l$ to $l+\Delta l$ produced by the breakage of fibers of $l_1$ are $2\alpha(l_1)\beta(l_1\rightarrow l)n(l_1,t)\Delta t\Delta l$, the item is obtained by integrating it from $l$ to $L$, the maximum length of fibers. Coefficient 2 is obtainable, assuming that $\beta(l_1\rightarrow l)$ is symmetrical function with respect to $l$.

Therefore, the following relation emerges:

$$n(l_1,t+\Delta t)\Delta l-n(l_1,t)\Delta l=-\alpha(l)n(l_1,t)\Delta l+2\int_{l_1}^{L} \alpha(l_1)\beta(l_1\rightarrow l)n(l_1,t)\Delta t\Delta l\quad \cdots \quad (1)$$

By dividing both sides of the equation by $\Delta t \Delta l$ and making $\Delta t \Delta l$ approach zero, we obtain the integro-differential equation, i.e.,

$$\frac{\partial n(l,t)}{\partial t} = -\alpha(l)n(l,t) + 2 \int_{l_1}^{L} \alpha(l_1)\beta(l_1\rightarrow l)n(l_1,t)dl_1\quad \cdots \quad (2)$$

This equation will be hereinafter referred to as the “breakage equation”.

We must remember that the definition of $n(l,t)$ means that $\int_{l}^{L} n(l,t)dl$ increases with time $t$ and agrees in the increase with the frequency of breakages occurred in unit weight of fibers in time $t$.

Consider the process in which such events as any one fiber breaks more than once can be ignored, defining the breakage ratio as the fraction of fibers broken throughout a process. Putting $t=0$, $\Delta t=1$ into eq. (1), the breakage equation is transformed as follows:

$$n(l,1)=n(l,0)-\alpha(l)n(l,0) + 2 \int_{l}^{L} \alpha(l_1)\beta(l_1\rightarrow l)n(l_1,0)dl_1\quad \cdots \quad (3)$$

where $n(l,0)$ is the initial distribution and $n(l,1)$ is the final distribution. This process will be hereinafter referred to as the “single stage breakage process”.

3. Solving the Breakage Equation

Now, slove eq. (2) for $n(l,t)$ under the initial condition of distribution. By applying the Laplace transformation to eq. (2), the breakage equation is transformed to following eq. (5), which is Volterra’s linear integral equation of the second kind having kernel $K$ expressed by

$$K(l_1, l_1, s)=\frac{\alpha(l_1)\beta(l_1\rightarrow l)}{s+\alpha(l)} \quad \cdots \quad (4)$$

which is

$$n(l,s)=n(l,0) + \int_{l_1}^{L} \alpha(l_1)\beta(l_1\rightarrow l)n(l_1,0)dl_1\quad \cdots \quad (5)$$

where, $n(l,s)$ is Laplace transform of $n(l,t)$.

To solve the eq. (5) is comparatively easy in the case of a specific kernal and a little complex in the general cases. Even if the solution is found, its inverse transform is rather complex. For this, we consider simple process and then, deal with the general process.

3-1. Where $\alpha(l)=k/l^n$, $\beta(l_1\rightarrow l)=1/l_1$

The expression for $\alpha(l)$ indicates that longer fibers are the breakage-prone, and for $\beta(l_1\rightarrow l)$ indicates that breakage occurs evenly along the fiber axis. The solution of this process is the basis of later theoretical evolution, as we shall see.

Differentiating eq. (5) with respect to $l$, results in:

$$\frac{\partial n(l,s)}{\partial l} + k(n+2)\frac{n-1}{s+kln}n(l,s) + \alpha(l)n(l,0)\quad \cdots \quad (6)$$

By applying the inverse Laplace transformation to the solution of above differential equation, we obtain,

$$n(l,t)=e^{-ktn}n(l,0) + 2 \int_{l}^{L} l_1^{n-1}g(l, l_1, t)n(l_1,0)dl_1\quad \cdots \quad (7)$$

Vol. 15, No. 6 (1969)
where $g$ is

$$g(l, l_1, t) = \frac{L^{-1} \left( (s+kl^n)^{\frac{2}{m}} - 1 \right)}{(s+kl^n)^{\frac{2}{m}} + 1}$$  \hspace{1cm} (8)$$

It is difficult to calculate eq. (8) about arbitrary $n$ directly, however, it is possible to obtain with series form solution by expanding the image function with respect to $s$. The solution by this method is included in the solution made in 3-2, as a matter of cause. Therefore, we discuss only the simpler cases in this section, assuming $m=2/n$ where $m$ is a positive integer. In this case, eq. (8) transforms thus:

$$g(l, l_1, t) = \lim_{s \to kl^n} \frac{d^m}{ds^m} (s+kl^n)^{m-1} e^{st}$$  \hspace{1cm} (9)$$

As the examples:

(i) Assuming $n=2$,

$$n(l, t) = e^{-kt^2} (n(l, 0) + 2kt \int_l^{l_1} n(l_1, 0)dl_1)$$  \hspace{1cm} (10)$$

(ii) and assuming $n=1$,

$$n(l, t) = e^{-kt} (n(l, 0) + 2kt \int_l^{l_1} n(l_1, 0)dl_1)$$  \hspace{1cm} (11)$$

3-2 General Processes

The two fractions, i.e., $\alpha(l)$ and $\beta(l \to l_1)$, in the everyday process are not so easily obtainable as preceding section 3-1 suggests. We, therefore, discuss a solution in a case where these fractions are generally given.

Assuming the solution of breakage equation to be,

$$n(l, s) = \sum_{n=0}^{\infty} 2^n \Phi_n(l, s)$$  \hspace{1cm} (12)$$

and substituting this into eq. (5), we find that $\Phi_n$ ought to satisfy the following relations,

$$\Phi_0(l, s) = \frac{n(l, 0)}{s + \alpha(l)}$$

$$\Phi_n(l, s) = \int_l^{l_1} K(l, l_1, s) \Phi_{n-1}(l_1, s)dl_1$$  \hspace{1cm} (13)$$

With the integral operator $A$ defined as,

$$\Phi_1(l, s) = A \Phi_0(l, s) = \int_l^{l_1} K(l, l_1, s) \Phi_0(l_1, s)dl_1$$  \hspace{1cm} (14)$$

eq (12) can be presented by following series,

$$n(l, s) = \Phi_0(l, s) + \sum_{n=1}^{\infty} 2^n A^n \Phi_0(l, s)$$  \hspace{1cm} (15)$$

Transforming this into time domain, the solution is obtained as

$$n(l, t) = e^{-\omega l^2} n(l, 0) + \sum_{n=1}^{\infty} 2^n B^n \phi_n$$  \hspace{1cm} (16)$$

where $B^n \phi_n$ is

$$B^n \phi_n = L^{-1} A^n \Phi_0(l, s)$$  \hspace{1cm} (17)$$

$\phi_n$ is

$$\phi_n = \frac{\pi (l_2)}{1 + \alpha(l) s + \alpha(l_2) s}$$  \hspace{1cm} (18)$$

and the operator $B$ is defined as

$$B \Phi_1 = \int_l^{l_1} \alpha(l_1) \beta(l_1 \to l_1) \Phi_1 dl_1$$

$$B^n \phi_n = \int_l^{l_1} \alpha(l_1) \beta(l_1 \to l_1) \int_l^{l_1} \alpha(l_1) \beta(l_1 \to l_1) \Phi_1 dl_1$$

$$\cdots$$  \hspace{1cm} (19)$$

The calculation of eq. (18) is easy, however, merely substituting it into eq. (16) is not realistic. For this reason, assuming $\alpha(l)t$ to be small and expanding eq. (18) into the power series of $\alpha(l)t$ lead to a concrete solution of eq. (16), as follow:

$$n(l, t) = e^{-\omega l^2} n(l, 0) + 2 \int_l^{l_1} \alpha(l_1) \beta(l_1 \to l_1) n(l_1, 0) dl_1$$

$$+ \frac{t^2}{2!} \left[ \int_l^{l_1} \alpha(l_1) \beta(l_1 \to l_1) \alpha(l_1) n(l_1, 0) dl_1 \right]$$

$$+ 2 \int_l^{l_1} \alpha(l_1) \beta(l_1 \to l_1) \int_l^{l_1} \alpha(l_2) \beta(l_2 \to l_1) n(l_2, 0)$$

$$dl_2 dl_1$$  \hspace{1cm} (20)$$

Assuming $\alpha(l)t$ to be small is considered reasonable for the purpose of this article, in that it deals with breakage in the spinning process.

Eq. (20) is identical with the solution on the process discussed in 3-1. This is easily brone out by calculating the terms of eq. (20), respectively. The first term of eq. (20) is identical with the solution obtained if the second term of the right-hand side of eq. (2) is zero. Clearly, then, it indicates the number of fibers unbroken after time $t$. Accordingly, the second and subsequent terms express the number of fibers generated by breaking.

Further expanding eq. (20) with respect to $\alpha(l)t$, the following is obtainable:

$$n(l, t) = n(l, 0) - t I_1(l) + \frac{t^2}{2!} I_2(l) - \frac{t^3}{3!} I_3(l) + \cdots$$  \hspace{1cm} (21)$$
where \( I_i(l) \) is
\[
I_i(l) = a(l)n(l, 0) - 2 \int_{l}^{L} a(l_1) \beta(l_1 \rightarrow l)n(l_1, 0) dl_1
\]
\[
I_i(l) = a(l) I_{i-1}(l) - 2 \int_{l}^{L} a(l_1) \beta(l_1 \rightarrow l)I_i(l_1) dl_1
\]
............... (22)

\( I_i(l) \) shows the final distribution, if the single stage breakage process with initial distribution \( I_{i-1}(l) \) is taken into account. Thus, the solution, when approximated to the second terms, agrees with the single stage breakage process.

If the integration of the right-hand side of the breakage equation is possible, the existence of a solution and convergences of eq. (20) and eq. (21), are obvious. It is also obvious that the smaller values of \( a(l)t \) (especially smaller degree of dependence of \( a(l) \) upon \( l \)) leads to the faster convergence.

4. Variation in Moment of Distribution

The fiber length distribution in an arbitrary time is the process where the two fractions are obtainable by calculating eq. (20) or (21). In many cases, however, we want to find two fractions, i.e., \( a(l) \) and \( \beta(l \rightarrow l) \), when the initial and final distribution are already known.

A conceivable method to do so is to consider that the moment of the final distribution is strongly influenced by two fractions. By this method, Meyer et. al. discusses a case where the breakage ratio is proportional to the fiber length and presents successful results.

The \( m \)-th moment denoted by \( M_m(t) \) in time \( t \) is expressed from the definition of the moment, as follows:
\[
M_m(t) = \frac{1}{N(t)} \int_{0}^{T} l^m n(l, t) dl
\]
............... (23)

Substituting eq. (21) into eq. (23), the following is obtainable:
\[
M_m(t) N(t) = M_m(0) N(0) - \int_{0}^{T} l^m I_1(l) dl
- \frac{t^2}{2^2} \int_{0}^{T} l^m I_2(l) dl - \ldots
\]
............... (24)

where \( N(t) \) is zero-th moment, i.e., the total number of fibers in a unit weight.

Now, let \( \beta_o(x), \quad (0 \leq x \leq 1) \), to be the distribution of breaking points of fibers of unit length. Then, since
\[
\beta(l \rightarrow l) = \frac{1}{l_o} \beta\left( \frac{l}{l_o}\right)
\]
............... (25)

and from this
\[
\int_{0}^{T} l^m \int_{0}^{T} a(n)\beta(l_1 \rightarrow l)I_1(l_1) dl_1 dl
- \int_{0}^{T} l^m a(n)I_1(l) dl \int_{0}^{L} x^m \beta_o(x) dx
\]
............... (26)

eq. (24) is reduced as follows:
\[
M_m(t) N(t) = M_m(0) N(0)
+ \beta_m \int_{0}^{T} l^m n(l, 0) dl
- \frac{t^2}{2^2} \int_{0}^{T} l^m \beta(l_1 \rightarrow l)I_2(l) dl + \ldots
\]
............... (27)

where
\[
\beta_m = 2 \int_{0}^{L} x^m \beta_o(x) dx - 1
\]
............... (28)

If \( m \geq 0 \), \( \beta_m \) for arbitrary \( \beta_o(x) \) takes the value of \(-1\) to 1.

(i) Where \( m = 1 \).
If \( m = 1 \), then \( \beta_1 = 0 \). Therefore, the mean fiber length \( \bar{l}(t) \) is easily yielded and is
\[
\bar{l}(t) = N(0) \bar{l}(0)
\]
............... (29)

This is a natural result, because the loss of fibers is ignored in this discussion.

(ii) Where \( m = 0 \).
If \( m = 0 \), then \( \beta_0 = 1 \). Therefore, the total number of fibers in unit weight at time \( t \) is
\[
N(t) \leq N(0)(1 + t M + \frac{t^2}{2!} M^2 + \ldots)
\]
............... (30)

Defining \( M \) as
\[
M = \max a(l)
\]
............... (31)

the upper bound of \( N(t) \) is expressed as following:
\[
N(t) \leq N(0)(1 + t M + \frac{t^2}{2!} M^2 + \ldots)
= N(0) e^{t M}
\]
............... (32)

The equality symbol is valid if the breakage ratio is independent of \( l \).

5. The Moment where \( a(l) = k l^n \)

Assuming the breakage ratio is proportional to \( l^n \), i.e., \( a(l) = k l^n \), which agrees comparatively with experimental results and using the results cited in the previous chapter, we discuss about the distribution of breaking points.

Substituting \( k l^n \) into eq. (27), the following is obtainable:
\[
M_m(t) N(t) = N(0) C M_m(0)
+ t k \beta_m M_m(0) + \frac{t^2}{2^2} k^2 \beta_m \beta_m M_m(0) + \ldots
\]
............... (33)
This shows that moment after time \( t \) is expressible by the sum of products of the moment of the initial distribution and the moment of distribution of breaking points.

Replacing \( \beta_0(x) \) with Pearson's (Type I) distribution which agrees in tendency with experimental results that the breaking points are apt to be generated around the center of fiber, we discuss the characteristic of \( \beta_m \). Pearson's distribution is expressed by following:

\[
\beta_0(x) = c \cdot (1-x)^2 . \tag{34}
\]

Fig. 1 shows \( \beta_0(x) \) at \( f = 0, 1, 2, \) and \( 3 \). Assuming \( f = 0 \), then \( \beta_0(x) = 1 \). This may be called "random breakage".

Fig. 2 shows \( \beta_m \) as a function of \( m \) for these distributions. It is clear the more breakage-prone around the center are the higher the gradual speed toward \(-1\). The dotted lines in Figs. 1 and 2 are not very realistic, but are intended to illustrate the proneness to breakage of fibers at leading ends. In this case, the function is given by

\[
\beta_0(x) - 3(2x-1) . \tag{35}
\]

6-1. Method of Experiments

The used fibers were 1.5 den, regular viscose staple with nominal length each 120, 90 and 50 mm. The sample fibers were adequately opened manually in advance and then carded repeatedly. The purpose of pre-opening was to prevent the steady state in the process from being disturbed by the differences in the degree of opening during different rounds of carding.

The fiber length was measured sampling 1,000 to 2,000 fibers from the same sample and measuring them with a rule in unit of mm.

6-2. Breakage Ratio

The experimental fiber length distributions are given in Figs. 5 to 9. Where no(l, t) is defined as

\[
n_0(l, t) = \frac{1}{N(t)} n(l, t) . \tag{38}
\]

It is clear from the figures that the longer fibers, more breakage-prone, therefore we assume again \( n(l) = kl^n \).

One conceivable way to obtain the breakage ratio is to use the following equation to express the number of fibers unbroken even after the process, as

\[
n(l, t) = e^{-\alpha(l)t} n(l, 0) . \tag{37}
\]

The fibers to be near the nominal length are not only the unbroken fibers, but include the broken fibers having the breakage points near the leading end of original fibers. For this reason, it is required to find a proper method to distinguish experimentally either being the broken fibers or not. One of the methods considered is
to use the sample fibers having been dyed both leading ends by some fluorescent dystuff. In this article, however, the calculation of breakage ratio was carried out by using the approximate estimation of the unbroken fibers. As shown in Fig.3, if we take $l_1$ in such a way as to make $L-l_1$ to sufficiently small compared with $L$, and then look at the fibers exceeding $l_1$ in length, we shall find that breakage ratio conforms approximately to $kl$. And we assume that $\beta_0(x)=1$.

From the assumptions, eq. (11) is reduced to following to express the number of fibers exceeding $l_1$:

$$\int_0^L n(l,t)dl=N_1(t)$$ ........................... (39)

where $N_1(t)$ is defined as

$$N_1(t)=N_1(0)e^{-klt} \left(1+kt \bar{I}_1(0)-ktl_1 \right) \cdots$$ (40)

which, by the 2nd order approximation with respect to $kt$ transforms into:

$$N_1(t)=N_1(0)(1+kt \{\bar{I}_1(0)-2l_1\})$$

$$-k^2 t^2 l_1 \left\{\bar{I}_1(0)-\frac{3l_1}{2} \right\} \cdots$$ (41)

by which it is possible to obtain $kt$. Here $\bar{I}_1(0)$ is the initial mean of lengths exceeding $l_1$. This method is believed to have high-degree precision for a initial distribution with the small variance of lengths such as is used in this experiment.

Table 1-A shows the results of calculation by eq. (41). Here, we defined that $t$ agrees with the number of carding rounds when $t$ takes an integer. The correlation between the variations of estimated $k$ within the same nominal length and the frequency of carding is hardly noticeable. This shows that the manual pre-opening to keep the steady state of the process was meaningful. If the breakage ratio is proportional to $l$, the value of $k$ ought to be invariable between different nominal lengths. But the results of Table 1-A show that the longer the nominal length, the higher the value. This means $n>1$.

The mark $\times$ in Fig. 4 shows the logarithms plotted for $kl_1(0)$ and $l_1(0)$. Since these points are well along the linear line, the breakage ratio seems to satisfy $kl^n$ as far as our experiments are concerned. We obtained $n=2.50$ to calculate the gradient. The forgoing is a case where $\beta_0(x)=1$. It is clear from Figs. 5 to 9 that the breaking points concentrate around the center of fiber axis. Therefore, the above results seem to overestimate the breakage ratio.

Bearing this in mind and assuming the absence of fibers of length $l_1$ to $l_1-L$ which, after breakage, are still similar in length to this range, eq. (38) may be used. Approximating eq. (38) to 2nd order and putting $l_1$ into $l$, the following is obtainable:

$$N_1(t)=N_1(0)(1-kt\bar{I}_1(0)+k^2t^2\frac{l_1^2}{2}\bar{I}_1(0)) \cdots$$ (42)

where $l_1^2(0)$ is the initial 2nd moment exceeding $l_1$.

The value $k$ obtained from this relation is shown by the mark $\bigcirc$ in Fig. 4 and Table 1-B. Naturally, $k$ is smaller than if eq. (41) is used and is 2.57.

After all, the breakage ratio is proportional to $k^{2.5-2.6}$. Consequently, the following equation will be used hereinafter for calculation:

$$\alpha(l)=kl^{2.5-2.6}$$ ........................... (43)

$k$ in this case should be $2.43 \times 10^{-6}$, averaging the value from two calculation methods.

6-3. Distribution of Breaking Points

Assuming eq. (43) to be breaking ratio, $\beta_m$ calculated from eq. (36) and (20) is plotted by mark $\times$ in Fig. 2. They are almost on the line $J=1$. And mark $\bullet$ shows $\beta_m$ calculated by the first order approximation of eq. (33). These plots are almost on the line $J=0$. The former estimate for $m\beta$ is smaller than latter, which is clarified to consider the second term being positive when $m>1$. Consequently, we will use the following hereinafter:

$$\beta_0(x)=6x(1-x)$$ ........................... (44)
6-4. Calculated Distribution after Carding

Figs. 5 to 9 show, with tangent lines, results obtained by numerical calculation of eq. (21) where both functions are given by eq. (43) and (44) and a sample before carding is taken as the initial distribution. The histogram shown by dotted lines is the initial distribution and solid line shows the measured value after carding. Table 2 compares measured values with calculated values of total number $N(t)$, average length $\bar{l}(t)$ and average length $l_w(t)$ on the weight-frequency distribution.

The calculated values agree generally with measured values. But, comparing calculated with measured distribution, we cannot overlook the fact that there are discrepancies having following two common tendencies:

a) The calculated value for extremely short fibers is high. This is mainly because, the shorter the fiber, the more loss-prone it is, during carding and sampling.

b) The calculated value near a quarter of a nominal length is low and the one near three quarter is high. This means that the number of fibers having been broken down more than once, are more than the number of fibers expected by the theory. It is difficult to explain this fact reasonably, bearing in mind P.P. Townend's findings that, in the blending of long and short fibers, more long fibers break than when long fibers alone are used.

If $J=2$, comparing with result when $J=1$, the discrepancy (a) is generally small but the over all agreement is decrease.

### Table 1 Estimated values of Breakage ratio

| Cut length (mm) | 0~1 round $l_1(0)/k$ | 1~2 rounds $l_1(0)/k$ | 2~3 rounds $l_1(0)/k$ | Average $l_1(0)/k$ | $n=2.5$ | $n=2.6$

Fig. 5 Experimental distribution of fiber lengths where nominal length is 60mm and frequency of carding $t=3$. 

7. The Process with Loss of Fibers

Theories described as far ignore the loss of fibers. It is clear from the results of our experiments, however, we must take the fiber loss in account to express more precisely the breakage process. For this, consider the process with loss of fibers.
Here, the loss ratio \( \gamma(l) \) is defined as follow:

\( \gamma(l)t: \) The fraction of fibers of length \( l \) that are lost in time \( dt \).

It is reasonable that this is a decreasing function with \( l \).

Using this function, the following equation corresponding to breakage equation (2) is obtainable:

\[
\frac{\partial n(l, t)}{\partial t} = -\{(a(l) + \gamma(l))n(l, t) + 2\int_{l}^{L} a(l_1) \beta(l_1-l) n(l_1, t) dl_1 \} \cdots (45)
\]

which, when solved, makes a solution corresponding to eq. (20), thus:

\[
n(l, t) = e^{-\int_{0}^{t} \gamma(l') \partial l'} n(l, 0) + 2\int_{0}^{t} a(l_1) \beta(l_1-l) \partial l \int_{l}^{L} a(l_2) \beta(l_2-l_1) n(l_2, 0) dl_2 dl_1 \cdots (46)
\]

where \( \gamma(l) \) is
Further treatment of this is reserved for inquiring at a later date.

8. Acknowledgments

The author thanks Prof. S. Ishikawa and Associate Prof. T. Ogawa of the Tokyo Institute of Technology, and Prof. J. Shimizu of Yamagata University for their guidance in our research. Special thanks are due to Mr. Y. Nakajima, Fujii Keori KK for his assistance in our experiments.

Literature cited

Note [1]: The relation of $n(l, t)$ and a weight-frequency distribution $w(l, t)$ is

\[ \epsilon(l) = a(l) + \gamma(l) \] .............................. (47)

By the use of this, we can easily convert it, the relation obtained in this article, into the expression with the weight frequency distribution.

For instance, eq. (2) transforms thus:

\[ w(l, t) = \frac{\alpha(l) w(l, t)}{l} \]

Note [2]: Eq. (32) is deducible directly from eq. (2). Integrating eq. (2) from $l$ to $L$, since the integration of the 2nd term becomes zero, the following obtainable:

\[ \frac{\partial N(l)}{\partial t} = \int_{l}^{t} a(l) n(l, t) dl \]

As $n(l, t) \geq 0$, therefore, we can find such $\xi$ to be $0 \leq \xi \leq L$ as being satisfied as follows:

\[ \frac{\partial N(l)}{\partial t} = a(\xi) N(l) \]

Solving this, the following upper limit for the total number of fibers is obtainable:

\[ N(l) = N(0) e^{(l/L - N(0) e^{mt}} \]
