ABSTRACT — Several studies have demonstrated the chemopreventive role of ketoconazole in animal models of liver injury. However, the underlying molecular mechanisms of this hepatoprotective effect are poorly understood. The present study assessed the potential of ketoconazole to enhance resistance to carbon tetrachloride-induced hepatotoxicity in vivo in a rat model. Ketoconazole pretreatment adult male rats were intraperitoneally injected with carbon tetrachloride for 24 hr and various hepatic parameters were analyzed. We observed decreased serum transaminases activity, reduced nuclear RelA/p65 expression, and suppressed production of pro-inflammatory cytokines in the liver tissue. Histopathological examination demonstrated ketoconazole pretreatment to extensively prevent liver injury. In addition, it significantly increased nuclear factor-erythroid 2 p45-related factor 2 (Nrf2) protein expression, glutathione (GSH) to oxidized glutathione (GSSG) ratio, and antioxidant enzymes gene expression. These results suggest that ketoconazole pretreatment ameliorates carbon tetrachloride-induced acute liver injury in rats, signifying its anti-inflammatory and antioxidant functions.

Key words: Ketoconazole, Carbon tetrachloride, Acute liver injury, Aryl hydrocarbon receptor, Nuclear factor erythroid 2-related factor 2, Adaptive response

INTRODUCTION

The liver is the largest metabolic organ in the human body that is involved in detoxification and excretion of waste material, functions that are fundamental to the survival of any living entity. Liver injury is commonly observed in clinical settings. Carbon tetrachloride (CCl4) is a typical hepatotoxicant, which is widely used to induce acute liver injury or chronic liver fibrosis in experimental rodents, owing to the similarity of its molecular mechanism with humans (Zhang et al., 2017). Many studies have demonstrated that CCl4 is metabolized into a highly reactive trichloromethyl free radical by cytochrome P450 2E1 (CYP2E1) in liver, thereby triggering lipid peroxidation as early as 2 hr after CCl4 intoxication. Therefore, severe inflammatory response and oxidative stress are the hallmarks of CCl4-induced liver injury (Peng et al., 2018; Lee et al., 2015).

Aryl hydrocarbon receptor (AhR) is an evolutionarily old, ligand-activated transcription factor that belongs to the bHLH/PAS (basic helix-loop-helix/Per-Arnt-Sim) family and controls the transcription of a large set of genes. It can be activated by a number of low molecular weight chemicals, ranging from environmental pollutants to dietary chemicals. AhR has long been known to be a cytosolic sensor that is involved in biotransformation and detoxification of small molecules. Currently, it is viewed as a protein with an important functional role in cell and organ development, peripheral and intestinal immunity, and cancer (Esser and Rannug, 2015). It is also involved in regulating the inflammatory response as well as disease tolerance. Generally speaking, sustained or uncontrolled activation of the AhR by tetrachlorodibenzo-p-dioxin (TCDD), coplanar polychlorinated biphenyls (PCBs), and polycyclic aromatic hydrocarbons (PAHs) exposure have been linked to an enhancement of inflammatory signaling, while transient or constitutively low levels of AhR activity may inhibit cytokine production in certain cell types and in vivo models (Beischlag et al., 2008). For example, treatment with β-naphthoflavone, an AhR agonist,
repressed the dbcAMP/theophylline-induced astrocytic differentiation of C6 glioma by inhibiting generation of the interleukin 6 (Takanaga et al., 2004). AhR-deficient mice become more sensitive to lipopolysaccharide (LPS) than wild-type mice (Bessede et al., 2014). Moreover, the possible interplay between the AhR and antioxidant role has been explored to a limited extent.

Nuclear factor-erythroid 2 p45-related factor 2 (Nrf2) has been considered as an essential protective factor against oxidative stress; it is known to control adaptive responses to various environmental stressors. Under homeostatic conditions, it is sequestered in the cytosol by binding to kelch-like ECH associating protein 1 (Keap1). During exposure to electrophiles and oxidative toxicity, Nrf2–Keap1 complex is disrupted, and Nrf2 is rapidly transferred to the nucleus, where it binds the antioxidant response elements (AREs) (Nioi et al., 2003; Itoh et al., 2004). The crosstalk between Nrf2 and AhR has been extensively studied. AhR-mediated target gene expression levels of AhR and its downstream genes and proteins in the mouse embryonic fibroblasts from Nrf2−/− mice and Nrf2−/− mice share some common phenotypes (Korashy et al., 2007; Tsuji et al., 2010). The crosstalk between Nrf2 and AhR is hypothesized that KCZ pretreatment might have protective effects on CCl4-induced acute liver injury in a rat model.

### MATERIALS AND METHODS

#### Animal and environmental conditions

A total of 48 male Sprague-Dawley (SD) rats, weighing 220 ± 20 g, were purchased from the experimental animal center of the Guangzhou University of Chinese Medicine (Animal permit number: SCXK [Yue] 2013-0034). The animals were fed food and water ad libitum under controlled laboratory conditions (temperature, 25 ± 1°C; humidity, 60 ± 10%; and a 12/12 hr light/dark cycle). The rats were acclimated to the laboratory conditions for at least 5 days prior to the experiment. All procedures involving animals were approved and were conducted under the regulations of the Committee on Care and Use of the Guangzhou University of Chinese Medicine, China.

#### Chemicals and their preparation

Carbon tetrachloride was purchased from Tianjin Fu Yu Fine Chemical Co., Ltd (Tianjin, China). KCZ (1-(4-(4-(((2R,4S)-2-((1H-imidazol-1-yl)methyl)-2-(2,4-dichlorophenyl)-1,3-dioxolan-4-yl)methoxy)phenyl)piperazin-1-yl)ethanone) was procured from the Aladdin Industrial Corporation (Shanghai, China). All other chemicals and reagents were of analytical grade and commercially available. For the experiments, all chemicals were prepared immediately before treatment; CCl4 was dissolved in paraffin oil, whereas KCZ was dispersed in 0.6% sodium carboxymethyl cellulose (CMC-Na). The dosage of CCl4 and KCZ was established according to previous experiments (Yuan et al., 2018; Minamiyama et al., 2004).

#### Animal treatment

The rats were randomly divided into four groups (12 rats per group) as follows: (I) control: rats were gavaged with vehicle only, (II) model: rats were injected with a single intraperitoneal (i.p.) dose of CCl4-paraffin oil mixture (50% CCl4, v/v, 2 mL/kg body weight), (III) KCZ pretreatment: rats were treated with KCZ (100 mg/kg body weight, p.o.) once a day for 3 days and injected a single i.p. dose of CCl4-paraffin oil mixture (50% CCl4, v/v, 2 mL/kg body weight) 3 hr after the last gavage, and (IV) KCZ only: rats were administered KCZ (100 mg/kg body weight, p.o.) once a day for 3 days. Rats were sacrificed 24 hr after CCl4 challenge under sodium pentothal anesthesia. The blood was collected from abdominal aorta, and a portion of liver tissue specimens were stored at −80°C till further analysis.

#### Histopathological examination of liver

A part of liver specimen was fixed in 10% formalin...
solution for 48 hr. It was then embedded in paraffin and sliced into 5-μm-thick sections using the microtome, followed by staining with hematoxylin and eosin (H & E). The tissue sections were then examined under a bright field microscope at different magnifications.

**Serum liver enzyme analysis**
Serum was obtained by centrifugation at 2000 rpm for 5 min within 1 hr after blood collection. Activities of aspartate aminotransferase (AST) and alanine aminotransferase (ALT) were measured immediately using an automatic biochemical analyzer and commercially available enzymatic assay kits (Beijing Strong Biotechnologies Inc.; Beijing, China).

**Measurement of TNF-α, IL-1β, and IL-6**
Concentrations of cytokines, namely tumor necrosis factor (TNF)-α, interleukin (IL)-1β, and IL-6, were determined using enzyme-linked immunosorbent assay (ELISA) kits (Cusabio Biotech Co., Ltd., Wuhan, China) according to the manufacturer’s instructions. Briefly, frozen liver tissue samples were washed with phosphate-buffered saline (PBS; pH 7.2). Samples were homogenized in a glass homogenizer in PBS (10% w/v), and then kept overnight at −20°C. Homogenized samples were then subjected to freeze–thaw cycles twice to disintegrate the cell membranes, following which the homogenate was centrifuged at 5000 g at 4°C for 5 min. The supernatant was then removed and subjected to ELISA immediately.

**Determination of glutathione**
The contents of reduced glutathione (GSH) and oxidized glutathione (GSSG) were measured using a commercially available kit according to the manufacturer’s instructions (Beyotime Institute of Biotechnology; Shanghai, China). The absorbance value was monitored at 412 nm on a microplate reader.

**RNA isolation and quantification**
Total RNA was extracted from liver samples using RNAiso Plus (Takara Bio Inc., Shiga, Japan). Purity of RNA was verified by gel electrophoresis and RNA concentrations were measured spectrophotometrically at 260 nm. Total RNA (2 μg) was reverse-transcribed into first-strand cDNA using PrimeScript RT Master Mix (Takara Bio Inc.). Real-time polymerase chain reaction (PCR) was conducted with SYBR Premix Ex TaqII (Takara Bio Inc.). All procedures were performed according to the manufacturer’s protocol. Relative gene expression was calculated using ΔΔCT method according to a previous study (Pfaffl, 2001). Table 1 lists the sequences of PCR primers used in this study.

Note: AhR: aryl hydrocarbon receptor. AhRR: aryl hydrocarbon receptor repressor; CYP1A1: cytochrome P450 1A1; GSR: Glutathione-disulfide reductase; GSTa: Glutathione S transferase α; NQO1: NAD (P) H-quinone oxidoreductase 1; GAPDH: L-lactate dehydrogenase.

**Hepatic protein isolation and western blot analysis**
A frozen liver sample was cut into small pieces and homogenized in a glass homogenizer with commercially available protein extraction kit (KeyGen Biotech Co. Ltd., Nanjing, China). Protein concentrations were determined using the bicinchoninic acid (BCA) method, and a total of 40 μg protein was separated by electrophoresis and blotted onto a polyvinylidene difluoride (PVDF) membrane (Millipore, Cork, Ireland). The membranes were incubated with primary rabbit antibodies against rat HO-1, CYP2E1, Nrf2, Lamin B1, and GAPDH (Proteintech; 1:1,000 dilution) and NF-κB/P65 (CST; 1:1,000 dilution) at 4°C overnight. Then, the membranes were washed thrice and incubated with secondary antibodies (CST; 1:2,000 dilution) at room temperature for 1 hr. ImageJ software was used to measure the intensity of the bands in the membrane.

**Statistical analysis**
All data are expressed as mean ± standard deviation (SD). One-way analysis of variance and Student–Newman–Keuls multiple comparisons were used to analyze the differences among the groups using the software Stata (version 13.0). A P-value < 0.05 was considered significant.
to be statistically significant. Graphs were generated by GraphPad Prism software (version 6.0).

RESULTS

General histopathology examination

As shown in Fig. 1, hepatic histopathological examination in the KCZ-only treatment group revealed no degenerative signs as compared to the normal liver tissues of the vehicle controls. In contrast, CCl₄-treated rats demonstrated severe hepatocellular damage, characterized by large areas of necrotic tissue, severe loss of hepatic architecture together with a significant hepatocyte ballooning. Although these findings were also observed in the KCZ pretreatment group, the incidence and severity of histopathological lesions were less prominent in the model animals.

**KCZ affects serum enzyme levels**

As depicted in Fig. 2, CCl₄-challenged rats showed a
significant elevation of serum ALT and AST, as compared with the control group (P < 0.01). In contrast, activities of serum AST and ALT in the KCZ pretreatment group reduced considerably as compared with those in the model group (P < 0.01). The KCZ treatment alone caused slight elevations in ALT levels.

**KCZ suppresses pro-inflammatory cytokine production**

As shown in Fig. 3, CCl$_4$ intoxication caused significant increase in the levels of pro-inflammatory cytokines, such as TNF-α, IL-1β, and IL-6, in the liver tissue as compared with that in the control group (P < 0.01). These levels declined in the KCZ pretreatment group as compared with the model group (P < 0.01 or P < 0.05). KCZ treatment alone had no effect on the generation of pro-inflammatory cytokines.

**KCZ increases glutathione generation**

Fig. 4 demonstrates a mildly elevated hepatic GSH content in the model group as compared with the controls. However, treatment with KCZ resulted in a further elevation of GSH content than that in the KCZ-free rats (P < 0.05). Only oral KCZ caused a mildly higher level of GSSG compared with the control, but CCl$_4$-stimuli resulted in a significantly higher level of GSSG than the control (P < 0.01). Pretreatment with KCZ prevented GSSG production after CCl$_4$ challenge. Similarly, pretreatment with KCZ ameliorated GSH/GSSG ratio in the liver (P < 0.05). The above data suggested that KCZ could induce a mild oxidation stress but alleviate the serious intracellular oxidation status resulting from CCl$_4$ exposure.

**KCZ increases AhR, CYP1A1, and AhRR mRNA expression**

We used quantitative PCR to examine the effects of
KCZ affects antioxidant enzyme gene expression

To further determine whether expression of AhR–Nrf2-related genes was affected, a quantitative RT-PCR analysis was performed that revealed mRNAs of glutathione-disulfide reductase (GSR), glutathione S transferase α (GSTa), and NAD(P)H-quinone oxidoreductase 1 (NQO1). As shown in Fig. 6, GSTa gene was found to be down-regulated 5-fold after CCl4 challenge (P < 0.01), whereas pretreatment with KCZ reversed this down-regulation induced by CCl4. A single dose of CCl4 challenge failed to change the mRNA expression of GSR and NQO1; however, KCZ-only administration significantly increased the levels of GSR and NQO1 mRNAs as compared with the control group (P < 0.05 or P < 0.01). Administration of KCZ in combination with CCl4 challenge also resulted in a slight elevation versus the control.
or model group (P < 0.05).

**KCZ affects protein levels of HO-1, Nrf2, and NF-κB**

We next examined the protein levels of heme oxygenase (HO)-1, CYP2E1, Nrf2, and NF-Kb/p65 by western blotting to determine whether KCZ could induce the Nrf2/ARE pathway during CCl4-induced liver injury. As shown in Fig. 7, there were no significant differences among the control, model, and KCZ-only treatment groups in HO-1 protein levels; however, pretreatment with KCZ following CCl4-intoxication augmented the expression levels of HO-1 (P < 0.05). Both KCZ-treated animals showed a higher level of Nrf2 protein in the nuclear than those in the KCZ-free rats (P < 0.05). Elevated levels of nuclear NF-κb/p65 protein were observed in the model group than other groups (P < 0.05). CCl4-intoxication obviously suppressed CYP2E1 expression (P < 0.05); however, pretreatment with KCZ relieved CYP2E1 suppression after CCl4 challenge.

**DISCUSSION**

Ketoconazole is an anti-fungal agent that was approved as a drug against a broad range of fungal infections in 1981; however, severe hepatic side-effects associated with it led to its restricted use (Maertens, 2004; Gupta and Lyons, 2015). Several lines of evidence indicate that KCZ could transform into a toxic metabolite, N-deacetyl-ketoconazole (DAK), which had a greater intrinsic toxicity than the original compound (Rodriguez et al., 1999; Rodriguez and Acosta, 1997). In our current study, we found that KCZ treatment alone could cause a slight increase in the ALT and GSSG levels; however, pretreatment with KCZ ameliorated CCl4-induced liver injury in rats, suggesting preconditioning to be one of the mechanisms. Preconditioning (also named adaptive response) is a phenomenon in which a prior exposure to an appropriate low dose of a toxic agent or stress could resist the toxic effects exerted by a subsequent harmful exposure of the same, a related, or an unrelated toxin/stress (Calabrese, 2016). It was reported that a prior low dose of CCl4 induced a state of refractoriness to a subsequent much higher dose of CCl4 (Ugazio et al., 1972). So far, LPS is one of the most frequently reported conditioning agents. For instance, pretreatment with nonlethal LPS dose has been shown to exert protective effects, manifested by attenuation of tissue injury and prolonged survival (Szabó et al., 1994; Bautista and Spitzer, 1995). A recent research found that exposure to LPS activated AhR, consequently leading to a down-regulation of early inflammatory gene expression, which, in turn, protected the mice against subsequent stimuli. Another study demonstrated bacterial pigments that serve as virulence factors, activate the host defense mechanism against acute and chronic bacterial infections upon binding to AhR (Moura-Alves et al., 2014). In AhR knock-out mice, apoptotic cells induce transcription of inflammatory cytokines genes in the macrophages leading to the development of autoimmune diseases. Apoptotic cells activate AhR in mouse macrophages and dendritic cells by the generation of immunomodulatory cytokine IL-10, which blocks inflammatory response and maintains normal physiological homeostasis (Shinde et al., 2018). These findings...
demonstrated the role of AhR in contributing to adaptive response. Ketoconazole has been identified as an activator of AhR (Korashy et al., 2007; Novotna et al., 2014). It is therefore possible that the protective effect of pretreatment with KCZ against CCl₄-induced liver injury in rats may involve AhR signaling.

CYP1A1 is considered to be a prototypical target gene of AhR. Our study revealed KCZ treatment to enhance CYP1A1 mRNA expression, which is consistent with previous studies (Korashy et al., 2007; Novotna et al., 2014). AhR-mediated adaptive response may involve the inhibition of NF-κB, which contributes to the production of inflammatory cytokines. Research confirmed that activation of AhR signaling pathway could promote proteasome-mediated degradation of RelA/p65 protein following its ubiquitination, thus inhibiting the production of inflammatory cytokines (Domínguez-Acosta et al., 2018). Apart from the canonical NF-κB pathway, AhR can regulate the expression of RelB, a component of the alternative pathway, which diminishes the inflammatory reaction (Baglole et al., 2008). CCl₄ exposure affects various intracellular signaling pathways. For instance, it activates the NF-κB signaling pathway resulting in a release of various pro-inflammatory mediators (Yamada and Fausto, 1998; Kiso et al., 2012). In the present study, we found that KCZ pretreatment reduced the generation of pro-inflammatory cytokines following CCl₄ intoxication following CCl₄-intoxication rats. According to the results of our study, KCZ pretreatment with CCl₄-intoxicated rats. Reduced GSH is a major endogenous antioxidant produced by cells, whereas its oxidized form GSSG is indicative of oxidative stress. As a marker for the intracellular redox equilibrium, we employed GSH/GSSG ratio to evaluate the oxidative stress. We found that KCZ-pretreated rats could effectively inhibit the decrease in the GSH/GSSG ratio induced by CCl₄ intoxication.

Ketoconazole is a widely accepted inhibitor of p450, and CCl₄ is metabolized by CYP2E1 in the liver into toxic free radicals. Some relevant studies have explored the effects of ketoconazole on CYP2E1 enzyme activity. Rats were given KCZ (140, 280, 420 μmol/kg·d⁻¹) for 7 days and had no significant inhibitory effect on activity of CYP2E1 in the liver (Cao et al., 2007). Another study revealed that KCZ did not markedly inhibit CYP2E1 activity at low concentration but could inhibit CYP2E1-catalyzed activity at high concentration in human liver microsomes (Zhang et al., 2002). Recent study also demonstrated KCZ had no inhibition effect on CYP2E1 activity in human liver microsomes (Krasulova et al., 2016). It seems that KCZ may be not specific for CYP2E1 inhibitor. In our study, we did not find KCZ to inhibit CYP2E1 protein expression, but we found pretreatment with KCZ alleviated the inhibitory effect of CCl₄ on CYP2E1 protein levels. We also found CCl₄ challenge resulted in down-regulation of AhR mRNA, whereas KCZ treatment up-regulated AhR mRNA expression. The mechanism remains unclear; one possible mechanism is the autoregulation of AHR expression by its own agonists. However, this is not a definite explanation (Harper et al., 2006). Anyway, alterations in AhR expression may have physiological and toxicological consequences (Engler et al., 2012).

It seems that activation of AhR–Nrf2 pathway promotes the host resistance to subsequent harmful exposure;
Ketoconazole pretreatment ameliorates acute liver injury

However, this was not the case. Notably, Nrf2 activation follows a biphasic dose–response relationship—a protective effect at low dose is followed by adverse responses at high doses. TCDD, a potent agonist to AhR, was reported to exacerbate liver damage when administered to mice 48 hr before CCl₄ challenge (Mejia-Garcia et al., 2013); this reinforces the notion that adaptive response is based on several key factors related to the characteristics of the conditioning agent and dosage, together with protective windows. Normally, a certain level of Nrf2 activation in healthy cells is beneficial in maintaining homeostasis; however, cancer cells appear to hijack Nrf2-mediated antioxidant to deal with various stresses, such as metabolic stress, mitotic stress, and oxidative stress, which promote the tumorigenic state (Kensler and Wakabayashi, 2010).

In conclusion, we first demonstrated the protective effect of KCZ, which ameliorated CCl₄-induced liver injury in an animal model. A possible mechanism of this effect could be activation of coupled AhR and Nrf2 gene batteries. Although KCZ lacks potential to develop into a hepatoprotective agent owing to its well-known hepatotoxicity, AhR–Nrf2 might be considered as a promising new target for prevention of acute liver injury. The results of the present study also expand our insights into the pharmacological activity of KCZ. KCZ could serve as a promising medicinal tool to study the functions of AhR–Nrf2 pathway. In addition, our findings may pave the way for a better understanding of the mechanisms of some hepatoprotective agents.
