**ABSTRACT.** Composition of glycoconjugates was examined in small intestines naturally infected with *Isospora suis* in preweaned pigs by use of 21 biotinylated-labeled lectins with avidin-biotin-peroxidase complex method. As compared with control pig, staining of 18 lectins altered in jejunal villus brush border and goblet cells of pigs naturally infected with *I. suis*. These results indicate that *I. suis* infection alters carbohydrate residues on the jejunal intestines.

**KEY WORDS:** histochemistry, *Isospora suis*, lectin.

Coccidia are a common cause of diarrhea in most mammalian and avian species [3, 11]. Coccidiosis in nursing pigs is caused by the intracellular protozoan parasite, *Isospora suis*. Clinical signs in affected pigs include yellowish to greyish diarrhea, dehydration, and weight loss in 5- to 14-day old piglets with high morbidity and low mortality [3, 12, 13]. *Escherichia coli* was frequently isolated from the small intestines of the coccidially infected piglets [3, 7, 11]. *Eimeria tenella* and *Echinostoma caproni* infection altered glycoconjugates composition in intestinal mucosa and may facilitate bacterial adherence to intestinal brush border [1, 9]. Therefore, *I. suis* infection may affect host intestines and allow newly introduced *E. coli* to colonize in the intestine. However, the effect of *I. suis* infection on expression of jejunal glycoconjugates has not been investigated yet. The objective of the present study was to determine the alteration of glycoconjugate in the jejunal of pigs naturally infected with *I. suis* by lectin histochemistry.

Twenty 7-day-old Landrace-Large White cross-bred piglets naturally infected with *I. suis* were used in this study. All piglets were tested by histopathologic examination, culture, immunofluorescence, and polymerase chain reaction for transmissible gastroenteritis virus, porcine epidemic diarrhea virus, rotavirus, and *E. coli*. Ten 7-day-old conventional Landrace-Large White cross-bred pigs selected from five minimal disease herds were used as negative control. Segments of intestines were obtained from middle portion of the jejunum. The samples were fixed with neutral buffered 10% formalin. After fixation overnight, tissues were deparaffinized in xylene, hydrated through a graded series of alcohols to distilled water. Endogenous peroxidase was quenched with absolute methanol containing 0.3% hydrogen peroxide for 15 min. Each section was treated for 1 hr with one of 21 biotinylated lectins (Vector Laboratories, Burlingame, CA, U.S.A.) at a concentration of 10 µg/ml in phosphate buffered saline (PBS, pH 7.2). The lectins used, their acronyms, and major specific sugars are summarized in Table 1. The sections were washed three times with PBS and incubated for 1 hr with an avidin-biotin-peroxidase mixture (ABC Kit, Vector Laboratories). The sections were washed three times in PBS, and the final reaction product was produced by immersing the sections in a solution of 0.01% hydrogen peroxide and 0.05% 3,3′-diaminobenzidine tetrahydrochloride (DAB) in PBS for 15 min. The sections were lightly counterstained with Mayer’s hematoxylin, dehydrated through graded concentrations of ethanol and xylene, and mounted. Control tissues were processed without lectin.

*E. coli* was isolated from 12 pigs naturally infected with *I. suis*. Among 12 *E. coli*, 7 carried gene for F6, 2 carried gene for F4, 1 carried gene for F41. Two isolates did not carried any fimbrial or enterotoxin genes. Immunofluorescent tests for porcine epidemic diarrhea virus, transmissible gastroenteritis virus, and rotavirus were negative in the small intestines of all pigs used in this study.

Histopathological lesions in the jejunum of all affected piglets were similar. Villi showed various degrees of atrophy associated with changes in their apical epithelium. Coccydial organisms were present in variable numbers of the cells lining the villi and were mainly asexual stages (meronts and merozoites). Sexual stages were also present in some cases and identified as spherical or oval macrogamonts in different stages of maturity.

At the lectin concentration used, labeling was specific and reproducible; and non-specific background staining was minimal or absent. Lectin histochemical characteristics of jejunum are summarized in Table 1. The villi tip was used...
to determine the degree of staining for villus brush border. The positive staining reaction was recognized by the occurrence of brown reaction products on the cell membrane. Staining intensity of lectins were increased in jejunal villus enterocytes of pigs naturally infected with \( I. \) suis \( \) infection. Therefore, alteration in the composition of glycoconjugates affects bacterial adherence to the mucosal surface. For example, coccidial infection may induce an increase of mannose residues on the intestinal surface and allow adhesion of more \( S. \) Typhimurium to the intestine in poultry [1]. The significant increased reactivity of jejunal mucosa from \( I. \) suis-infected pigs as compared with those from normal pigs to glucose/mannose-specific lectin such as PSA implicates this glycoconjugate as a potential factor in the enhancement of intestinal colonization by \( E. \) coli following \( I. \) suis infection. It has been reported that porcine enterotoxigenic \( E. \) coli binds specifically to PSA [5, 14, 15]. The increased staining intensity of PSA that has high affinity for \( E. \) coli indicated that altered composition of glycoconjugates in pigs naturally infected with \( I. \) suis promote intestinal colonization by serving as a site for the adherence of \( E. \) coli strains. Therefore, alteration in the composition of glycoconjugates as the result of \( I. \) suis infection could be possi-
