ABSTRACT. Paramylon is a β-(1–3)-D-glucan isolated from Euglena gracilis Z. This study was designed to evaluate the protective effects of paramylon on liver injury induced by carbon tetrachloride (CCL4) in rats. Wistar strain male rats were orally administered paramylon (500, 1,000 and 2,000 mg/kg body weight) before treatment with a single intraperitoneal dose of 50% CCL4 (2 ml/kg body weight). The rats were sacrificed 24 hr later, and blood samples were collected for assay of serum biochemical parameters. The livers were excised to evaluate the activity of antioxidant enzymes. Histopathological examination of the livers was also performed. The results showed that the treatment of paramylon prevented elevation of the serum levels of hepatic enzyme markers and inhibited fatty degeneration and hepatic necrosis induced by CCL4. Pre-administration of paramylon reduced the liver apoptotic index. The treatment of paramylon recovered reductions of activity of hepatic superoxide dismutase, catalase and glutathione peroxidase induced by CCL4. These results demonstrate that paramylon exhibits protective action on acute hepatic injury induced by CCL4 via an antioxidative mechanism. To the best of our knowledge, this is the first report of a hepatoprotective effect based on the antioxidative action of paramylon.

KEY WORDS: antioxidation, carbon tetrachloride, hepatoprotection, liver injury, paramylon.

Paramylon is a β-(1–3)-D-glucan isolated from Euglena gracilis Z [7]. The yield of paramylon from Euglena gracilis Z amounts to approximately 60–70% of the dried cells. Native paramylon shows cytokine-related immunopotentiating activity [18]. Sulfated derivatives of paramylon and N, N-dimethylaminoethyl paramylon exhibit anti-human immunodeficiency virus (HIV) and antimicrobial effects [17, 29]. To the best of our knowledge, there has been no research reported on the antioxidative effect of paramylon.

β-glucans are structurally complex homopolymers of glucose found in the cell walls of fungi and cereal plants. Their beneficial effects on the immune system and the lack of toxic or adverse effects has focused studies on β-glucan molecules [38]. β-glucans are acknowledged to be one of the immune response modifiers [6]. Studies conducted over the past decade have shown that β-glucans inhibit tumor development [28, 38], enhance defense against bacterial infection [15, 24], activate macrophages [8], induce production of cytokines [10, 34], nitric oxide (NO) and arachidonic acid metabolites [14, 21], increase hematopoiesis [35], exert radioprotective effects [12], are effective against burns [9, 37], improve wound healing by inducing the macrophage release of wound growth factors [40] and lower serum lipids [4, 23]. Among the several mechanisms proposed for the protective effects of β-glucans, the major one is related to antioxidant capacity of the molecules [1, 20], which has been further proven by Kogan et al. [16] using electron paramagnetic response spectroscopy.

Carbon tetrachloride (CCL4) is an extensively used industrial solvent. It is used as an injury agent for animal experiments, and induces reactive oxygen formation and depletes Glutathione (GSH) of the phase II enzyme. It may reduce antioxidant enzyme and antioxidant substrates to induce oxidative stress. CCL4 induces liver injury caused by free radical and induces lipid peroxidation that can result in hepatic cell injury. Oxidative stress is an important factor in acute and chronic liver injury. The hepatotoxicity of CCL4 requires bioactivation by the cytochrome P450 (Cyt P450) phase I system in the liver and yields a reactive metabolic trichloromethyl radical (CCL3) and proxy trichloromethyl radical (OCCCL3). These free radicals can bind with polyunsaturated fatty acid (PUFA), and form alkoxy (R) and peroxy radicals (ROO) that can generate lipid peroxide, cause damage in the cell membrane, change enzyme activity and finally induce hepatic injury or necrosis [26, 27, 39].

We designed this study to investigate the possible protective effects against acute hepatic injury induced by CCL4 and its mechanism in rats based on the antioxidative action of paramylon, a β-(1–3)-D-glucan, isolated from Euglena gracilis Z.

MATERIALS AND METHODS

Preparation of paramylon: Paramylon isolated from Euglena gracilis Z was obtained from Euglena Co., Ltd.
CAT activity was assayed by the method of Smataxylin autoxidation [22] with a commercial kit (Northwest (GPx). Hepatic SOD activity was measured based on hemate (SOD), catalase (CAT) and glutathione peroxidase for estimation of the activities of hepatic superoxide dismutase. The unbroken cells and cell debris were removed by centrifugation at 4 \times 10^3 rpm at 4°C for 10 min, and clear supernatant was used for assay. The animals in groups IV, V and VI, respectively, were administered paramylon orally for 3 days at 500, 1000 and 2000 mg/kg body weight. The animals in groups I, II, III received CCl4 and blood and liver samples were immediately obtained.

Serum and liver biochemical assays: The blood samples were centrifuged at 3,000 rpm for 10 min at 4°C to obtain serum. Serum glutamic pyruvate transaminase (GPT) and glutamic oxaloacetate transaminase (GOT) levels were determined by the optimized ultraviolet method (GOT or GPT assay kit, Wako, Osaka, Japan). Liver homogenates (5% w/v) were prepared in cold 50 mM potassium phosphate buffer (pH 7.4). Liver samples were dissected out and washed immediately with ice cold saline to remove as much blood as possible. Liver homogenates (5% w/v) were prepared in cold 50 mM potassium phosphate buffer (pH 7.4). The unbroken cells and cell debris were removed by centrifugation at 2,000 rpm at 4°C for 10 min, and clear supernatant was used for estimation of the activities of hepatic superoxide dismutase (SOD), catalase (CAT) and glutathione peroxidase (GPx). Hepatic SOD activity was measured based on hematoxylin autoxidation [22] with a commercial kit (Northwest Life Science Specialties, Vancouver, BC, Canada). Hepatic CAT activity was assayed by the method of Smna et al. [33] with a commercial kit (Cell Tech, California, U.S.A.). Hepatic GPx activity was assayed by the method of Lagli et al. [25] with a commercial kit (Northwest Life Science Specialties, Vancouver, BC, Canada).

The amount of protein was measured with Bio-Rad Protein Assay Dye Reagent Concentrate (Bio-Rad Laboratories, Hercules, CA, U.S.A.) according to the method described by Bradford et al. [5].

**RESULTS**

The effects of pretreatment with paramylon on the CCl4-induced elevation of serum GOT and GPT are shown in Table 1. The serum GOT and GPT levels were found to be significantly elevated in rats administered CCl4. Treatment with paramylon at 1,000 and 2,000 mg/kg prevented the elevation of the serum levels of GOT and GPT induced by CCl4 (p<0.05; Table 1).

Figure 1 showed the effect of paramylon on CCl4-induced liver damage in rats. In the saline + CCl4-treated group, there were extensive degenerative and necrotic areas around the central vein of the liver. Pre-administration of paramylon could reduce these pathological changes dose-dependently (Fig. 1). Table 2 summarizes the data relating to liver damage induced by CCl4 in the pathological histology. Treatment of paramylon reduced the injury score of degeneration and hepatic necrosis (Table 2).

of paramylon reduced the liver apoptotic index (Fig. 2, Table 2: p<0.05). Histological examination of the liver showed the preventive effects of paramylon on CCl4-induced hepatic toxicity. Table 3 shows the effects of pretreatment with paramylon on the CCl4-induced decrease in the levels of hepatic antioxidant enzyme activity. The levels of hepatic SOD, CAT and GPx activity were significantly decreased in the rats of the saline + CCl4 group. Treatment with paramylon restored the levels of hepatic SOD, CAT and GPx activity (Table 3).

DISCUSSION

CCl4 hepatotoxicity depends on its reductive dehalogenation catalyzed by Cyt P450 in the endoplasmic reticulum of hepatic cells leading to the generation of the unstable complex trichloromethyl radical. The superoxide anion (O2·−), H2O2, and the hydroxyl radical (·OH) are reactive oxygen species (ROS) mainly produced in mitochondria [41]. Cells have a number of mechanisms to protect against the toxic effects of ROS including free radical scavengers and chain reaction terminators such as SOD, CAT and GPx systems [13, 41]. SOD removes O2·− by converting it to H2O2 that can be rapidly converted to water by CAT and GPx [13]. Cellular injury occurs when ROS generation exceeds the cellular removal capacity. In the present study, decreased SOD, CAT and GPx activities occurred in liver injury induced by CCl4, implying
Fig. 1. Effect of paramylon on CCl₄-induced liver damage of rats. Animals were treated with CCl₄ in the presence and absence of paramylon as follows: (a) saline + CCl₄, (b) paramylon (500 mg/kg) + CCl₄, (c) paramylon (1,000 mg/kg) + CCl₄ and (d) paramylon (2,000 mg/kg) + CCl₄. In the saline + CCl₄-treated group (a), there were extensive degenerative and necrotic areas around the central vein of the liver. Treatment with paramylon reduced the sizes of these damaged areas dose-dependently (b, c, d). *=central vein. HE stain, bar=150 μm.

Fig. 2. Effect of paramylon on apoptosis in the liver. (a) Saline + CCl₄, (b) paramylon (500 mg/kg) + CCl₄, (c) paramylon (1,000 mg/kg) + CCl₄ and (d) paramylon (2,000 mg/kg) + CCl₄. In the saline + CCl₄-treated group (a), there were more ssDNA-positive cells than in the paramylon + CCl₄ groups (b, c, d). *=central vein. Immunohistochemistry with ssDNA, bar=50 μm.
downregulation of numerous enzymatic oxidative reactions in the cytosolic compartments and mitochondria. Furthermore, liver damage via the ROS pathway caused remarkable increases in the GOT and GPT levels in serum and histological changes in hepatic cells. Paramylon exhibited its protective effect on liver injury in response to CCl₄ by elevating SOD, CAT and GPx activities to increase scavenging of ROS in mitochondria, leading to decreased activity of GOT and GPT.

In previous studies, oral administration of β-glucan showed protective effects against oxidative tissue damages induced by sepsis, burn, pressure ulcer, ischemia/reperfusion or drugs such as acetaminophen and methotrexate in rodents through its antioxidant properties [3, 30–32, 36, 37]. The aforementioned studies showed that β-D-glucan increased the activities of antioxidant enzymes, such as SOD, CAT, GPx and GSH, and inhibited lipid peroxidation. β-glucan receptor activity has been reported for a variety of other leukocytes, including macrophages, neutrophils, eosinophils and NK cells, as well as for nonimmune cells including endothelial cells, alveolar epithelial cells and fibroblasts [6]. Nonopsonic recognition of β-glucans by these cells has been ascribed to multiple receptors [2], and indeed a number of β-glucan receptors have been identified, including complement receptor type 3, lactosylceramide, scavenger receptor and Dectin-1. However, in these receptors, only Dectin-1 has been clearly shown to have a role in mediating the biological response to β-glucans [6]. Thus, in the present study, paramylon exhibited a protective effect against liver injury via β-glucan receptors such as Dectin-1 receptor.

In conclusion, our results demonstrated the protective effect of paramylon against CCl₄-induced liver injury via its antioxidative action. To the best of our knowledge, this is the first report of a hepatoprotective effect based on the antioxidative action of paramylon. Our results support the potential use of paramylon in clinical conditions where oxidative organ failure may be present. Further studies with paramylon receptors and transduction pathways should be conducted to highlight the underlying mechanisms of this protective effect.
