(Received for publication on March 17, 1997)

Abstract. Conventional therapy for renal cell carcinoma using interleukin 2 (IL-2) has shown limited antitumor action. The purpose of our study was to investigate synergistic antitumor effects of IL-2 and Xiao-Chai-Hu-Tang (XCHT), and to elucidate the mechanisms of interaction between the two drugs against the murine renal cell carcinoma cell line, Renca, in vivo. The treatment was started 5 days after subcutaneous transplantation of Renca tumor. XCHT was given at a dose of 2.5g/kg daily for 30 days orally. IL-2 was given at a dose of $10^4$ U/mouse by subcutaneous injection every other day 8 times. Combination of XCHT and IL-2 inhibited growth of the tumor and prolonged survival significantly as compared with the untreated mice. Increased cellular infiltration was observed in tumor tissue and the lungs of mice treated with XCHT alone and by combination of XCHT and IL-2, but there were no histological changes in the liver and kidney. Elevation of serum IL-6 was observed in tumor-bearing mice, but IL-6 was significantly suppressed by administration of XCHT. The results obtained suggest that combination of XCHT and IL-2 induces enhanced immunological reaction in specific organs and tissues, and IL-6 may have a role in the synergistic effect of these two agents. It was concluded that combination of XCHT and IL-2 is useful in the treatment of patients with renal cell carcinoma. (Keio J Med 46 (3): 132-137, September 1997)

Key words: Xiao-Chai-Hu-Tang, interleukin 2, interleukin 6, Sino-Japanese medicine, renal cell carcinoma

Introduction

Renal cell carcinoma is a relatively common tumor, accounting for approximately 3% of adult malignancies. Currently, the only chance for cure of renal cell carcinoma is early detection and surgical resection. However, approximately 30% of patients have metastatic disease at the time of diagnosis, and 50% of those treated for cure by radical nephrectomy eventually develop either local recurrence or distant metastases. Once the disease has become metastatic or recurrent, renal cell carcinoma carries a poor prognosis with 74% mortality at 1 year and 96% mortality at 3 years. This is due to the absence of effective therapy for patients with advanced renal cell carcinoma. None of the hormonal or chemotherapeutic agents so far tested has given an objective response rate greater than 15% by monotherapy.

Interleukin 2 (IL-2), originally discovered as a T-cell growth factor, is a lymphokine produced by helper T lymphocytes. Treatment of tumor-bearing mice or patients with IL-2 alone, or combined with the adoptive transfer of lymphocytes activated by IL-2, has been shown to induce regression of the tumors. However, conventional systemic IL-2 therapy has shown only limited anti-tumor activity.

Xiao-Chai-Hu-Tang (XCHT) is a traditional Chinese medicine composed of hot water extracts from 7 species of medical plants, Bupleuri Radix, Pinelliae Tuber, Scutellariae Radix, Zizyphi Fructus, Ginseng Radix,
Glycyrrhizae Radix and Zingiberis Rhizoma, and has been used as an antipyretic medicine. A recent study utilizing biochemical technology disclosed that XCHT has various pharmacological actions including anti-inflammatory, anti-viral, immunomodulating effects, and has been shown to have an anti-tumor activity as a biological response modifier property.

The purpose of our study was to investigate synergistic antitumor effects of IL-2 and XCHT, and elucidate the mechanisms of interaction between the two drugs in murine renal cell carcinoma cell line.

Materials and Methods

Animals

Female BALB/c mice were purchased from Charles River Japan Inc. (Kanagawa, Japan). The animals were kept in established pathogen-free condition animal cages and fed a commercial pellet diet CE-2 (CLEA Inc., Tokyo, Japan). For all experiments, 6-week-old mice were used.

Tumor cells

Renca, which is a transplantable murine renal cell carcinoma of spontaneous origin, was established at the National Cancer Institute, USA, and was a generous gift from Dr T Fujioka (Iwate Medical University, Morioka, Japan).

Tumor transplantation

The masses of Renca tumors were excised from mice and cut into about 3 mm x 3 mm x 3 mm pieces. Then each fragment was implanted subcutaneously into the back of a mouse with a trocar needle.

Interleukin 2

The recombinant human IL-2 was produced by Shionogi & Co. Ltd. (Osaka, Japan). The titer of the IL-2 was evaluated via 3H-thymidine incorporation of the CTLL-2 cell line and expressed in Japan reference units.

Xiao-Chai-Hu-Tang

XCHT (Sho-saiko-to®), was obtained from Tsumura & Co. Ltd. (Tokyo, Japan). It was prepared by boiling 7 authenticated herbal drugs with hot distilled water in the following proportions: 7.0 g Bupleuri Radix, 5.0 g Pinelliae Tuber, 3.0 g Scutellariae Radix, 3.0 g Zizyphi Fructus, 3.0 g Ginseng Radix, 2.0 g Glycyrrhizae Radix and 1.0 g Zingiberis Rhizoma. Aqueous extract was filtered, spray-dried, and 4.5 g of spray dried extract is equivalent to the human daily dose of decoction. This extract was stored at 4°C until redissolution in distilled water at a concentration of 1 g/100 ml for use. XCHT was almost soluble in water and the solution with a small amount of insoluble debris was provided to mice as drinking water for 30 days ad libitum.

Experimental therapy model

Five days after tumor implantation, mice were separated into groups consisting of seven mice each after randomization and therapy was started. IL-2 was dissolved in phosphate-buffered saline (PBS) and a 0.2 ml portion of the solution was administered by subcutaneous injection at a dose of 10^4 U/mouse every other day, 8 times. The dose of IL-2 for combination therapy with XCHT was established as a minimal but significantly effective dose from a dose-finding test with doses varying from 5 x 10^3 U/mouse to 5 x 10^4 U/mouse. XCHT was given to the mice as drinking water daily for 30 days. The perpendicular diameters of the tumors were measured with a sliding caliper and the tumor weights were estimated by the formula, (long diameter) x (short diameter)^2/2.

IL-6 determination

IL-6 levels in the serum were measured by an enzyme-linked immunosorbent assay (ELISA). Ten days after initiation of treatment with XCHT and/or IL-2, blood was taken from the retroorbital sinus. The serum was subjected to ELISA for the determination of IL-6 using a Cytoscreen™ mouse IL-6 Kit (BioSource International, Camarillo, CA, USA). The concentration of IL-6 was given as the average level from four mice.

Histopathological analysis

Histopathological changes of the tumor were analyzed in 4 groups, including untreated mice, consisting of 3 mice each. Mice were sacrificed by decapitation under light ether anesthesia 10 days after initiation of the treatment with IL-2 and/or XCHT, and the tumors, lungs, livers and kidneys were resected, fixed and stained with hematoxylin-eosin.

Statistical analysis

Statistical analyses were carried out based on growth ratios to tumor volumes before treatment in each group using the Student’s t-test. Survival rates were calculated by the Kaplan-Meier method and the statistics determined by the Wilcoxon rank sum test. A P value of less than 0.05 was considered statistically significant.
Results

Daily dose of XCHT

The aqueous solution of XCHT was exchanged every second or third day and the consumption was measured. The average daily intake of this solution by each mouse was 4.9 ml for the 15 days after initiation of the therapy, and the daily dose of XCHT was calculated to be 2.5 g/kg from weights of mice at the initiation of the treatment. Water consumption was not influenced by addition of XCHT to drinking water.

Antitumor activity

Dose dependent antitumor effects are shown in Table 1. IL-2 at a dose of $5 \times 10^3$ U/mouse had a tendency to inhibit growth of the tumor, however, it was not significant. On the other hand, IL-2 at doses of $1 \times 10^4$ U/mouse and $5 \times 10^4$ U/mouse significantly inhibited growth of the Renca tumor ($P < 0.05$). Based on the result of the dose finding test, $1 \times 10^4$ U/mouse of IL-2 was employed in combination therapy with XCHT.

Effects of XCHT and IL-2 on the growth of the tumor are shown in Table 2. XCHT did not significantly inhibit growth of the tumor. IL-2 significantly inhibited growth of the tumor ($P < 0.05$). The antitumor effect was most pronounced in the mice treated with the combination of XCHT and IL-2, and was significantly different compared to mice treated with XCHT or IL-2 alone ($P < 0.05$). XCHT and IL-2 are considered to have a synergistic antitumor effect when T/C value of mice treated with XCHT (83%) × T/C value of mice treated with IL-2 (68%) is greater than that of mice treated with both drugs in combination, where T is mean tumor weight of the treated mice and C is mean tumor weight of the untreated mice. Fifteen days after initiation of treatment, the T/C value of mice treated with XCHT × T/C value of mice treated with IL-2 was 56.4. On the other hand, the T/C value of mice treated with both drugs in combination was 21.1. Results showed that the combination of XCHT and IL-2 has a synergistic antitumor effect.

Treatment with XCHT or IL-2 alone did not extend the survival of mice, but survival was significantly ($P < 0.05$) extended in mice treated with both drugs in combination (Fig 1).

Serum IL-6

IL-6 concentrations in the serum were determined by ELISA in non tumor-bearing mice and tumor bearing mice treated with XCHT and/or IL-2. IL-6 was undetectable in mice to which Renca tumor had not been

transplanted. IL-6 concentrations were significantly lower in mice treated with XCHT alone than in untreated tumor-bearing mice. Serum IL-6 concentrations decreased by administration of IL-2 alone or combination of XCHT and IL-2 but there was no significant difference compared with untreated tumor-bearing mice. Rates of IL-6 concentration to tumor weights were then compared between each treatment group. The ratio in mice treated with XCHT alone was much lower than that in mice of other treatment groups (Table 3).

Table values are mean ± SD for 4 mice; *XCHT was administered orally daily, for 10 days, at a dose of 2.5 g/kg/day; IL-2 was administered subcutaneously every other day, 5 times, at a dose of 10⁴ U/mouse. Blood was collected 10 days after initiation of the therapy. †p < 0.05 vs untreated tumor-bearing mice; ‡p < 0.05 vs IL-2; ‡p < 0.05 vs XCHT.

Histopathological analysis

Tumors, lungs, livers and kidneys were removed ten days after initiation of treatment and stained with hematoxylin-eosin. In the tumors of mice treated with XCHT, IL-2 or combination of XCHT and IL-2, enlargement of nuclei and loosened intercellular connection of tumor cells were observed. Marked cellular infiltration and scattered loss of tumor cells were observed in mice treated by combination of XCHT and IL-2 (Fig 2). Cellular infiltration and alveolar wall thickening were observed in the lungs of mice treated with XCHT and in mice treated with the combination of XCHT and IL-2 (Fig 3), but there were no histological changes in the liver and kidney (data not shown).

Discussion

Recently, it has been generally recognized that XCHT has a biological response modifier property. XCHT was shown to increase pokeweed mitogen-induced production of IL-1β, IL-6 and granulocyte-macrophage colony-stimulating factor (GM-CSF) by human peripheral blood mononuclear cells in vitro, and oral administration of XCHT augments natural killer (NK) activity in mice. We have expected that XCHT would have antitumor action in combination with IL-2 against renal cell carcinoma by activation of cytokine network of tumor-bearing animals or human. The present study has demonstrated that XCHT and IL-2 have a synergistic antitumor effect against Renca
tumor and prolong survival of tumor-bearing mice.

Hematoxylin-eosin staining of the livers and kidneys of mice treated with IL-2, XCHT, or combination of the two drugs showed no histopathological changes, in contrast, increased cellular infiltration was observed in tumor tissue and the lungs of mice treated with XCHT or by combination of XCHT and IL-2, despite our having avoided cervical dislocation or use of heavy anesthetics for sacrifice of the mice because these procedures may cause lung congestion.\textsuperscript{14}

It has been reported that pulmonary fibrosis following interstitial pneumonia is a serious side effect of concomitant administration of interferon (IFN) and XCHT administered to the patients with chronic active hepatitis.\textsuperscript{15} It has not been clarified whether IFN participates in development of pulmonary fibrosis by allergic reaction or pharmacological action of IFN itself, but Elias \textit{et al}.\textsuperscript{16} demonstrated that IFN controls proliferation of human fibroblasts \textit{in vitro}. Interstitial pneumonia caused by XCHT alone has been reported, and Tomioka\textsuperscript{17} suggested that this side effect was caused by allergic reaction to XCHT, analyzing bronchoalveolar lavage fluid and specimens obtained by transbronchial lung biopsy of the patient. Therefore, IFN and XCHT are considered to cause biological changes of the lung by additive effects. On the other hand, IL-2 is known to be an IFN-inducer. Handa \textit{et al}.\textsuperscript{18} demonstrated that IL-2 stimulates NK clones to proliferate, accompanied by IFN-\gamma production in the culture fluid.\textsuperscript{18} These reports may explain the histopathological changes observed in the lungs of mice treated with IL-2 and XCHT in the present study. Furthermore, it may suggest that concomitant use of XCHT and IFN, or IL-2, which is known to be an IFN-inducer, would enhance immunological reaction in the specific organs or tissue, including the lungs and tumor tissue.

IL-6 was detected in the sera of mice bearing Renca tumor. This elevation of serum IL-6 is considered to be due to production of IL-6 by Renca tumor itself or by host immune mediating cells in the results of reaction with tumor cells and IL-6, originally identified as a B cell stimulatory factor (BSF-2),\textsuperscript{19} has been demonstrated to have a variety of biological functions. IL-6 induces the terminal maturation of activated B cells to immunoglobulin-producing cells derived from T lymphocytes,\textsuperscript{19} stimulates acute phase protein synthesis in hepatocytes,\textsuperscript{20} acts on multipotential hematopoietic progenitors,\textsuperscript{21} and was shown to be an autocrine growth factor for human multiple myeloma\textsuperscript{22} and renal cell carcinoma.\textsuperscript{23} Blay \textit{et al}.\textsuperscript{24} reported elevation of serum IL-6 in 66 of 138 patients with advanced renal cell carcinoma, a poor prognosis in patients with elevated serum IL-6, and a poor response to IL-2 therapy in these patients. IL-6 is considered to have an important role in progression of renal cell carcinoma, consequently, suppression of serum IL-6 in mice by administration of XCHT may be beneficial in the treatment of Renca-bearing mice using IL-2.

Matsuura \textit{et al}\textsuperscript{25} reported that intraperitoneal administration of Bupleuri Radix, Pinelliae Tuber, Scutellariae Radix, Ginseng Radix, Glycyrrhizae Radix and Zingiberis Rhizoma, which are included in XCHT as its constituents, induced serum IL-6 in mice, though, in the present study, administration of XCHT reduced
serum IL-6 in Renca tumor-bearing mice. The discrepancy, between the present study and their results can, however, be explained by their having administered XCHT or its constituents to non tumor-bearing mice, or administering the agents intraperitoneally, while XCHT was given orally in our experiment.

The results obtained indicate that XCHT and IL-2 have a synergistic anti-tumor activity against renal cell carcinoma, though careful observation is needed for early detection of development of possible interstitial pneumonia in clinical application. XCHT has been used with the concept of traditional Chinese medicine for chronic active hepatitis and other inflammatory diseases, but concomitant use with IFN brought unexpected phenomena in clinical use. Clarification of the biological characteristics of XCHT and further investigation of the appropriate mode of administration based on basic and clinical studies may yield benefits in the treatment of patients with renal cell carcinoma.
