Abstract

SiAlON ceramics have been known for many years as prime candidate materials in structural applications at ambient and high temperatures involving superior mechanical and/or chemical processes. In spite of their excellent properties, the utilization of SiAlONs has remained limited till today due to the high cost of raw materials and processing. In order to circumvent this problem, low cost refractory grade, coarse, impure, less sinter active $\alpha\cdot\text{Si}_3\text{N}_4$ powder was used to produce SiAlON ceramics with satisfactory mechanical properties.

In this article, the processing challenges in the production of SiAlON ceramics with $\beta\cdot\text{Si}_3\text{N}_4$ powder were discussed. The process parameters obviously affect the phase assemblage, densification, microstructural and mechanical properties of final SiAlON ceramics. Processed $\beta\cdot\text{Si}_3\text{N}_4$ powder characteristics are majorly investigated by SEM-EDX, XRD, XRF, laser particle sizer and elemental analyser. The existence of undesirable impurities in the $\beta\cdot\text{Si}_3\text{N}_4$ crystal structure because of the use of impure $\text{Si}_3\text{N}_4$ powders has been shown to be tolerable by TEM microstructural analysis. Mechanical properties are in general evaluated by Vickers indentation method. Wear behaviour of the cost effective SiAlONs were compared with commercially available ceramic materials which are commonly being used in wear applications. Initially the use of such powders to produce materials for engineering applications proved challenging, however, satisfactory results have been obtained by the optimization of the initial chemical composition and process parameters.

Keywords: powder processing, $\beta\cdot\text{Si}_3\text{N}_4$ powder, particle size, sintering, characterization, wear

1. Introduction

SiAlON ceramic materials are very significant with their highly desirable, and proved potential, especially in industrial wear and high temperature applications¹². The final mechanical and chemical properties of these ceramics depend on microstructural evolution (grain size, grain aspect ratio, porosity, intergranular phase, impurities, etc.)¹⁷. Powder processing stage has a strong effect on microstructural development, since ceramic parts are produced by the sintering of initial powder mixtures³⁴¹². Removal of impurities from the raw powders, initial particle size distribution, homogeneous dispersion of sintering additives, and grinding of starting non-oxide powders are the important parameters in the microstructural formation of SiAlON materials with superior mechanical properties³⁴¹⁹. SiAlON production processes are based on homogenization of raw powders $\alpha$ or $\beta\cdot\text{Si}_3\text{N}_4$ powder, $\text{Al}_2\text{O}_3$, $\text{AIN}$ and sintering additives such as $\text{Y}_2\text{O}_3$, $\text{Sm}_2\text{O}_3$, $\text{Er}_2\text{O}_3$, $\text{Dy}_2\text{O}_3$, $\text{CaO}$, etc. in alcohol or water in order to achieve a predetermined composition ($\alpha:\beta\cdot\text{SiAlON ratio (}$\alpha'\cdot\beta'$), a determined intergranular phase chemistry),

followed by drying of slurry, shaping, and sintering.

Traditionally, high quality pure $\alpha$-Si$_3$N$_4$ powder is used instead of $\beta$-Si$_3$N$_4$ powder due to its higher sinter activity. However, fine $\alpha$-Si$_3$N$_4$ powders are very high in cost and this is a key determinant parameter for large scale applications. On the other hand, $\beta$-Si$_3$N$_4$ powders can be produced economically with combustion synthesis. Free silicon and iron may originate from milling of the raw $\beta$-Si$_3$N$_4$ powder. Removal of these impurities and/or achieving desired final phases including these impurities in the sintered product is required. Besides milling and sintering process parameters have crucial effects on micro-structural evolution. In this respect, SiAlON powder processing technology involves a number of know-how developments to produce materials with superior properties at low cost.

In this article, the manufacture low cost SiAlON ceramics with satisfactory mechanical properties by the use of low cost refractory grade, impure, less sinter active $\beta$-Si$_3$N$_4$ powder was described. Correlation between processed $\beta$-Si$_3$N$_4$ powder characteristics and process conditions with final phase assemblage, densification, microstructure and mechanical properties was determined.

2. Experimental Studies

In this study $\beta$-Si$_3$N$_4$ powder manufactured by combustion synthesis (Beijing Chanlian-Dacheng Trade Co. Ltd., China) was used as initial Si$_3$N$_4$ powder. Attrition milling in water with Si$_3$N$_4$ grinding media (3 mm in diameter) at 1400 rpm was performed to decrease the average particle size of $\beta$-Si$_3$N$_4$ starting powder. In order to completely understand correlation between processing-structure-property relationships, $\beta$-Si$_3$N$_4$ powder characteristics were investigated by using SEM-EDX, XRD, XRF, laser particle sizer and elemental analyser.

Since $\alpha$' and $\beta$' phases are both stable thermodynamically, it is possible to produce hard and tough $\alpha$-$\beta$-SiAlON composites. For this purpose 30 $\alpha$ :70 $\beta$-SiAlON composition was designed and Y-Sm-Ca multi cation doping system was chosen with the aim to produce self reinforcement microstructures. Y$_2$O$_3$ (>99.9%, H.C. Starck Berlin, Germany), Sm$_2$O$_3$ (>99.9%, Stanford Materials Corp., USA), CaCO$_3$ (>99.75%, Reidel-de Haen, Germany) were used as sintering additives. CaO was used to avoid $\alpha$ to $\beta$ SiAlON transformation, Y$_2$O$_3$ and/or Re$_2$O$_3$ (where Z$_{Re} \geq 62$) to increase the stability and hardness of $\alpha$-SiAlON and Sm$_2$O$_3$ (where Z$_{Sm} < 62$) to develop elongated $\beta$-SiAlON grains to increase fracture toughness). Si$_3$N$_4$ powders and sintering additives were mixed with high purity AlN powder (H Type, Tokuyama Corp, Japan, with 1.6wt% O content) and Al$_2$O$_3$ (Alcoa A16-SG Pittsburgh, USA). All of the prepared SiAlON compositions with $\beta$-Si$_3$N$_4$ powders were milled in water with 64wt% solid loadings. Tetramethylammonium hydroxide (TMAH) was used as a dispersant with 2.5 wt%. Milling was performed for a total duration of two hours. The slurry was sieved with 32 $\mu$m and homogenized together with 2 wt% plasticizer (Primal B60, Rhörm & Haas, Italy), 2 wt% binder (PEG 4000, Clarion Produkta GmbH, Germany) and 2 wt% lubricant (Zuzoplast Wem, ZSC Zimmer&Schwarz, Germany) in a mixer. The slurries were spray dried (Nubilosa LTC-2 model). The powders were uniaxially pressed at 25 MPa and subsequently cold isostatically pressed at 300 MPa to improve green density. Binder burn-out process was carried out at 550°C for 30 minutes. The pellets were sintered both by gas pressure sintering (KCE, FPW 100/150-2200-25 type furnace), under 2.2 MPa nitrogen gas in a stan-

![Flow chart of the manufacturing process.](image-url)
standard manner and by pressureless sintering (Thermal Technology, 1000-4560-FP2000 model furnace). Post sintering heat treatment was performed at 1900°C for 3 hours under 0.1 MPa nitrogen gas. Flow chart of the manufacturing process is given in Fig. 1.

\[ \alpha : \beta \] phase ratio and phase composition of the intergranular phase were determined by X-ray diffraction (Rigaku 2000 Rint, Japan). Polished surfaces of the sintered samples were gold coated prior to examination in a Zeiss VP50-Supra type scanning electron microscope (SEM) by using back-scattered electron imaging mode. Analytical TEM investigations were achieved by using 200 kV field emission TEM (JEOL JEM-2100F).

Hardness and fracture toughness measurements were carried out by Vickers indentation technique by applying 10 kg load for 10 seconds. At least 5 indentations were made for each sample. The sand blast wear tests were further performed at Röchling Leripa GmbH (Austria). The test conditions were given in Table 1. The erosion rates of the nozzles are defined as the nozzle mass loss divided by the nozzle density and so volume of the erodent abrasive particles (wear volume) is found.

Fig. 2 An XRD analysis of cleaned and as-received $\beta$-$\text{Si}_3\text{N}_4$ powders.

Fig. 3 Schematic illustration of iron and silicon removing processes.

contains Fe, Si, Fe$_2$Si and FeSi$_2$ as impurities. Iron contamination was believed to cause from the milling process of starting Si powder involving use of steel grinding media.

In order to remove iron, magnetic cleaning process was applied as shown in Fig. 3. Initial $\beta$-$\text{Si}_3\text{N}_4$ powder was mixed in mixer with isopropyl alcohol and Fe impurities were collected with a magnet. This process was repeated until iron impurities were totally removed. To remove silicon impurities, obtained slurry after magnetic cleaning process were passed under 75 µm sieves to separate coarser silicon particles. Subsequently slurry was dried in rotary evaporator. A phase comprises of as-received and cleaned $\beta$-$\text{Si}_3\text{N}_4$ powder is given in Fig. 2. XRD analysis showed that this cleaning process is effective, since there were no silicon or iron/iron containing impurities detected.

3.2 Effect of milling on powder characteristics

Initial average particle size of $\beta$-$\text{Si}_3\text{N}_4$ powder was measured as 10 µm by laser diffractometer (Fig. 4). Attrition milling in water with $\text{Si}_3\text{N}_4$ balls (3 mm in diameter) at 1400 rpm was performed to decrease the average particle size of $\beta$-$\text{Si}_3\text{N}_4$ starting powder to 1µm, 0.8 µm and 0.5 µm. The related powders were designated as B1 (d50: 1 µm), B0.8 (d50: 0.8 µm) and B0.5 (d50: 0.5 µm). For the milling process,
the ratio of powder to deionised water and dispersant was 800 g : 400 g : 16 g; the weight ratio of powder to Si₃N₄ milling balls was 1: 2.3. The vessel was cooled by water circulation throughout the process. The slurry temperature was systematically controlled every hour. If slurry temperature reaches 50°C, milling speed was decreased for the duration of the next 30 minutes. Milling efficiency was given in Table 2. In the first 1.5 hrs, particle size was down to 3.58 µm. After 7 hrs milling, particle size was down to 1.2 µm.

SEM analysis of as-received and milled β-Si₃N₄ powder was given elsewhere. As-received β-Si₃N₄ starting powder exhibited prismatic-elongated particle morphology, whereas the milled β-Si₃N₄ particles (B1, B0.8, and B0.5) showed an irregular morphology with sharp edges. The sum of initial Si₃N₄ powder characteristics were given in Table 3.

Total oxygen content of the powders was determined by the inert-gas-fusion method, using an elemental analyser. As-received β-Si₃N₄ powder contains 3 wt% oxygen. After 21 hours milling in water B0.5 powder has 7.8 wt% oxygen. This can be attributed to the hydrolysis of β-Si₃N₄ powder during milling in water after long hours. After 21 hours milling the slurry began to bubble with an ammonia odour. It was shown that the long term milling in isopropyl alcohol might have increased in the amount of Si-O-Si surface groups.

XRF analysis of B0.5 powder is given in Table 4. Fe, Ca, Mn, P, Sr, Cu, Ni and Cr are still present in very small quantities (less than 0.1 wt.%) in cleaned β-Si₃N₄ powder. XRF analyses verify the XRD analyses of cleaned β-Si₃N₄ powder. SEM-EDX elemental analyses of B0.5 powder showed the presence of Fe, Ca, Cu, Ba, S, Mn, Ti and Ni as impurities (Fig. 5).

3.3 Effect of milling time on SiAlON properties

3.3.1 Densification, phase assemblage and microstructure

Milling time is the most important variable that will effect final particle size, particle surface characteristics and hence densification, phase assemblage and microstructure. Table 5 shows some characteristics of the powders (B1, B0.8 and B0.5), sintering conditions and some properties after sintering process. It was found that SiAlON obtained from B1 powder, milled for 9 h presents nearly full densification and designed α:β phase ratio was achieved. Increase in milling time from 9 to 13h leads to increase in oxygen content of Si₃N₄ powder and this variation causes increase in β' content. During milling in water, following reaction may occur:

\[
\text{Si}_3\text{N}_4 + 6\text{H}_2\text{O} \rightarrow 3\text{SiO}_2 \text{ amorphous} + 4\text{NH}_3
\]

SiO₂ formation due to this reaction shifts the composition to β' rich region. It is also expected that increased silica would preferentially react with α-SiAlON stabilizing additives and thus would reduce/prevent α-SiAlON formation.

Other important topic is sintering of coarse B0.8 powder by pressureless sintering route at 1800°C, for

1 h with almost full densification due to judicious selection of dopant system\(^{23}\). One of the main aspects in designing SiAlONs with improved properties would be the chosen of additives that would provide a good liquid phase sintering behaviour. In this study Sm rich Y-Sm-Ca dopant system with cation molar ratio \(30:64:6\) was chosen because of the low eutectic temperature and high nitrogen solubility of the Sm-Si-Al-O-N system\(^ {24}\). Moreover, the viscosity of Sm-Si-Al-ON liquids is less than the other lanthanide containing SiAlONs and this makes densification easier\(^ {24}\). Further increase in milling time to 21 h results in further increase in oxygen content up to 7.8 wt.%. Higher oxygen content induces more liquid phase during sintering and leads to better densification even at 1850\(^\circ\)C but it has detrimental effect on high temperature properties due to higher liquid phase content.

**Fig. 6** BSE-SEM images of sintered SiAlONs prepared from (a) B1, (b) B0.8 and (c) B0.5 powders.

7.8 wt.%. Higher oxygen content induces more liquid phase during sintering and leads to better densification even at 1850\(^\circ\)C but it has detrimental effect on high temperature properties due to higher liquid phase content.

**Fig. 6** shows BSE-SEM images of sintered SiAlONs prepared from \(\beta\)-Si\(_3\)N\(_4\) powders which were subjected to different milling times. The differences in microstructure can be explained on the basis of differences in powder particle size and sintering conditions. The microstructure of B1 sample consisted of predominantly between 1-1.4 \(\mu\)m \(\alpha\) and \(\beta\)\(^+\) grains diameter, the aspect ratio of grains changes between 2.5 to 7 (Fig. 6a). The diameter and length of grains were determined by the SEM micrographs of polished surfaces. Over 200 grains of each sample were measured. The apparent aspect ratio of the grains was calculated by dividing the length to diameter. A decrease in \(\beta\)-Si\(_3\)N\(_4\) particle size to 0.8 \(\mu\)m (B0.8) resulted in decrease in \(\alpha\) and \(\beta\)\(^+\) grains diameter to between 0.5-1.5 \(\mu\)m, but aspect ratio of grains almost similar (Fig. 6b). This sample was subjected to heat treatment at 1900\(^\circ\)C for 3 hrs under 0.1 MPa nitrogen gas pressure. However, substantial grain growth was not achieved due to coarse grain size of sintered samples. In order to obtain grain growth, grain size should be less than 0.5 \(\mu\)m. It was observed that in order to achieve grain growth and to develop self reinforced microstructure after heat treatment, the grain size of SiAlON after sintering should be rather fine, preferably less than 0.5 \(\mu\)m as in Fig. 7 \(^{21}\). Otherwise, coarse grains, even around 1 \(\mu\)m, do not have enough driving force for grain growth. Similar observations were made on \(\beta\)-Si\(_3\)N\(_4\) ceramics\(^ {25-28}\).

After 21 hrs milling, particle size was down to 0.5 \(\mu\)m and B0.5 specimen after sintering have fine elongated microstructure with grain size was around 0.2 \(\mu\)m and aspect ratio was about 7. It is evident that final grain size of \(\beta\)-Si\(_3\)N\(_4\) derived SiAlON ceramics depends on the initial \(\beta\)-Si\(_3\)N\(_4\) particle size (Fig. 8). During sintering, the solution of \(\beta\)-Si\(_3\)N\(_4\) in the

</table>
liquid phase and precipitation as $\alpha:\beta$-SiAlON might have caused the formation of $\alpha:\beta$-SiAlON from $\beta$-Si$_3$N$_4$ powder. The nucleation can either be homogeneous from the liquid or heterogeneous on the existing $\beta$-Si$_3$N$_4$ grains. Given the fact that the initial particle size is an effective parameter on the final microstructure, the use of coarse or fine $\beta$-Si$_3$N$_4$ powders resulted in coarse or fine $\alpha:\beta$-SiAlON, respectively. It appears that nucleation of $\alpha:\beta$-SiAlON occurred heterogeneously on the pre-existing crystals in case of B0.8 and B1 powders.

Even if the starting $\beta$-Si$_3$N$_4$ powder was subjected to magnetic cleaning and sieving processes, some impurities may remain in powder. After a detailed TEM-EDX examination of the sintered SiAlON samples prepared from B1 powder, incorporation of undesirable Fe and Cr impurities into the $\beta$-SiAlON crystal structure was found (Fig. 9). As previously noted Be, Mg, Li and Ga may enter $\beta$-Si$_3$N$_4$ crystal structure. These results clearly showed that Fe and Cr can enter $\beta$-SiAlON crystal structure. As a conclusion it can be inferred that the use of Si$_3$N$_4$ powders with certain impurities can be used to produce a SiAlON phase microstructure.

### 3.3.2 Mechanical properties

The hardness and fracture toughness values of the SiAlON ceramics are summarized in Table 6. Increasing milling time resulted in a decrease in hardness. During milling in water, oxygen content of the composition increased. Therefore, the initial composition shifted to $\beta'$ region. In addition, higher oxygen content led to a higher fraction of intergranular phase. This increment provided a decrease in hardness. B1 and B0.8 have similar hardness values. The difference in hardness between B1, B0.8 with that of B0.5 can be attributed to the presence of larger fraction of grain boundary phase in B0.5 due to prolonged milling time and also to the absence of harder $\alpha'$ phase. Although B1 and B0.8 specimens consisted of both $\alpha'$ and $\beta'$ phases, hardness values were lower than expected. As mentioned before, incorporation of Fe and Cr impurities in $\beta'$ crystal structure might have caused a decrease in hardness values.

Both indent diagonals and crack lengths around the indentations were measured from the SEM images and found that $l/a$ ratio varies between 1.0 and 1.7 and such values indicated good crack growth resistance property of the investigated ceramics. The differences in microstructure and properties can be explained on the basis of differences in powder particle size. The development of more elongated grains
in B0.5 resulted in relatively higher toughness than other sintered ceramics. B1 and B0.8 samples have similar aspect ratio (see Fig. 6) and thus fracture toughness values are similar. Post sintering heat treatment did not have any effect on grain growth for B0.8 sample (Fig. 7). It was concluded that to achieve grain growth and to develop self-reinforced microstructures by heat treatment, grain size of SiAlON microstructure after sintering should be less than µm (preferably ≤ 0.5 µm). Coarse grains would not have enough driving force for grain growth.

3.3.3 Wear resistance

Table 7 presents the hardness, flexural strength, fracture toughness, phase assemblage and wear volume of the samples. Sand blast wear tests were carried out on the developed SiAlON ceramics to simulate wear caused by severe particle impacts. In addition the wear volume of the developed cost effective SiAlON was compared with commercial ceramic materials and ceramic sintered from coarse (0.8 µm) silicon nitride powder. Silica content on silicon nitride powder governed the phase assemblage. If oxygen content is ~7.8 wt%, the designed α’ : β’ ratio was not achieved and composition was shifted to β’ rich region. It was observed that initial particle size have vital effects on microstructural evolution. If particle size is larger than 0.5 µm low aspect ratio grains developed. A combination of hardness of around 14 GPa and indentation toughness of 5.1 MPam1/2 could be obtained in ceramics sintered from coarse (0.8 µm) β-Si3N4 powders. This SiAlON ceramics prepared by with commercial Si3N4, showed similar wear resistance performance and proved more durable than commercial alumina ceramics which are widely used in wear applications.

commercial Si3N4 proved advantageous over B0.8 sample. However, wear volume values are almost similar. In general, it can be concluded that SiAlON ceramics have better properties than Si3N4 ceramics for commercial applications.

4. Conclusions

In this article, processing challenges of β-Si3N4 powder to produce SiAlON ceramics have been tried to clarify. It has been found that undesired iron and silicon impurities in starting silicon nitride powder can be significantly reduced by magnet and then wet sieving. On the other hand, incorporation of undesirable impurities into the β-SiAlON crystal structure and thus use of Si3N4 powders with certain impurities as characterized by TEM, are found to be possible.

The effect of powder processing conditions on phase assemblage, densification, microstructure and mechanical properties of SiAlON parts has been identified. The powder milling time was determined to see the effects on creating silica on silicon nitride powder. Silica content on silicon nitride powder governed the phase assemblage. If oxygen content is ~7.8 wt%, the designed α’ : β’ ratio was not achieved and composition was shifted to β’ rich region. It was observed that initial particle size have vital effects on microstructural evolution. If particle size is larger than 0.5 µm low aspect ratio grains developed. A combination of hardness of around 14 GPa and indentation toughness of 5.1 MPam1/2 could be obtained in ceramics sintered from coarse (0.8 µm) β-Si3N4 powders. This SiAlON ceramics prepared by with commercial Si3N4, showed similar wear resistance performance and proved more durable than commercial alumina ceramics which are widely used in wear applications.

Hasan Mandal (Prof. Dr.) received his PhD in Ceramic Materials from University of Newcastle (UK) in 1992. In the period of 2007-2008, Dr. Mandal was at Karlsruhe University as Alexander von Humboldt Fellow. In 1996, he joined the Department of Ceramic Engineering at Anadolu University. He became the Head of Department (1999), Dean of the Faculty of Engineering (2004), Chairperson of Turkish Engineering Deans Council (2006), Chairperson of Global Engineering Deans Council (GEDC-2009), Vice Rector of Anadolu University (2010). He is currently is Vice President and also the Director of Research and Graduate Policies at Sabanci University/Istanbul. He has co-authored over a hundred publications, three patents about science and technologies on Si3N4 based ceramics including phase relationships, structure-property relations and applications. Because of these achievements, he was honoured by twenty awards including European Ceramic Society, Stuijts Award in 2005. He is a member of World Innovation Foundation and World Academy of Ceramics.

Nurcan Calis Acikbas

Nurcan Calis Acikbas received B.S., M.S. and PhD. Degrees in Ceramic Engineering from Anadolu University, Turkey in 2002, 2004 and 2009, respectively. She was with MDA Advanced Ceramics Ltd. from 2004 to 2010. She joined the Bilecik University, Mechanical and Manufacturing Engineering Department as assistant professor. She appointed as Deputy Director of Bilecik University Central Research Laboratory at 2011. She was honoured by award Turkey Technology Development Foundation (TTGV) the most successful thesis in university-industry collaboration. Her current research interest is structure-property relationship; tribology; Silicon Nitride based ceramics and its applications.
