The Behaviour of Solutions with Singularities on a Characteristic Surface to Linear Partial Differential Equations in the Complex Domains

By

Sunao Ouchi

§ 0. Introduction

Let \( L(z, \partial_z) \) be a linear partial differential operator defined in a neighbourhood \( \Omega \) of \( z=0 \) in \( C^{n+1} \). Its coefficients are holomorphic in \( \Omega \). Let \( K \) be a connected nonsingular complex hypersurface through \( z=0 \) and characteristic for \( L(z, \partial_z) \). We choose the coordinate so that \( K = \{ z^0 = 0 \} \). In the present paper we study the equation

\[
L(z, \partial_z)u(z) = f(z),
\]

where \( u(z) \) and \( f(z) \) are holomorphic in a sector \( \Omega(\theta_0) \) whose edge is \( K, \Omega(\theta_0) = \{ z \in \Omega ; z_0 = 0 \} ; |\arg z_0| < \theta_0 \}. \) It is the main purpose of this paper to show under some conditions on \( L(z, \partial_z) \) that if \( u(z) \) has at most some exponential growth on \( \Omega(\theta_0) \) and \( f(z) \) has an asymptotic expansion with bounds on \( \Omega(\theta_0) \) as \( z_0 \to 0 \), then \( u(z) \) has also an asymptotic expansion of the same type as \( f(z) \) (Theorems 1.5 and 1.7). The conditions on \( L(z, \partial_z) \) are given by means of characteristic indices \( \{ \sigma_i ; 0 \leq i \leq p \} \) of \( K \) and the localizations on \( K \) defined in [9]. The growth order of \( u(z) \) and the asymptotic expansion of \( f(z) \) are characterized by \( \sigma_{p-1} \). When \( f(z) \) has no singularities on \( K \), that is, it is holomorphic in \( \Omega \), the equation (0.1) was investigated in [12] and it was shown that \( u(z) \) is also holomorphic in \( \Omega \) under some conditions, which is contained in the results in this paper.

As for existence of solutions of (0.1) which are singular on \( K \) were investigated in many papers, for example, [1], [2], [3], [5], [10], [13], [15] and papers cited there.

In § 1 we give notations and definitions of characteristic indices and function spaces, and state the results. Theorems 1.11 and 1.13 are applied to the...
proves of Theorems 1.5 and 1.7. In §2 we study the function spaces introduced in § 1. In §3 we introduce an integro-differential operator $L_{a}(z, \lambda, \xi, \partial_{z}, \lambda \partial_{a} - \lambda \partial_{t})$, $0 < \alpha < 1$, which is derived from $L(z, \partial_{z})$, and construct a formal solution $V(z, t, \lambda)$ of an equation

\[(0.2) \quad L_{a}(z, \lambda, \xi, \partial_{z}, \lambda \partial_{a} - \lambda \partial_{t})V(z, t, \lambda) = F(z, t, \lambda)f_{n_{a}}(\xi + t z_{i}).\]

In §4 we construct the kernel functions $G(\phi; w, z, t)$ and $G_{R}(\phi; w, z, t)$ in Theorem 1.11, where we use $L_{a-1}(z, \lambda, \xi, \partial_{z}, \lambda \partial_{a} - \lambda \partial_{t})$, $\alpha_{p-1} = (\sigma_{p-1} - 1)/\sigma_{p}$. In §5 we investigate integral operators acting on holomorphic functions on a sector and the proof of Theorem 1.11. It is the main purpose in §6 to give Theorem 6.28 which is used to show Theorem 1.5 in §7. We give an integral representation of $u(z)$ in (0.1) in order to prove Theorem 6.28, where $L_{a}(z, \lambda, \xi, \partial_{z}, \lambda \partial_{a} - \lambda \partial_{t})$, $\alpha_{i} = (\sigma_{i} - 1)/\sigma_{i}$, is used. The representation in this paper is somewhat different from that in [6] and [7], and sufficient for our purpose. The arguments in §6 are similar to those in [12]. But we investigate the equations under the weaker conditions than in [12]. We used the operator $L_{a}(z, \lambda, \xi, \partial_{z}, \partial_{t})$ in [12], which does not contain $\lambda \partial_{a} - \lambda \partial_{t}$. Since we treat (0.2) in this paper, the arguments become somewhat complicated. In §7 firstly we summarize about majorant functions and show Theorem 1.13. Next we give the proofs of Theorems 1.5 and 1.7. We make use of Theorems 1.11 and 6.28 in the proof of Theorem 1.5, and Theorem 1.7 follows from Theorems 1.5 and 1.13. Finally we give the proofs of estimates, that is, the proofs of Propositions 4.1 and 6.8, which are assumed in the preceding arguments. Proposition 4.1 (Proposition 6.8) gives estimates of functions appearing in construction of $G(w, z, t)$ (resp. in the representation of $u(z)$). Many constants will appear in this paper. So for simplicity we denote various constants by the same notations $A, B, C$, etc..

§1. Notations and Definitions

The following usual notations are used: $z=(z_{0}, z_{1}, \ldots, z_{n})=(z_{0}, z_{1})$ is an element of $C^{n+1}$, while $\xi=(\xi_{0}, \xi_{1}, \xi')=(\xi_{0}, \xi')$ is the variable dual to $z$, $\partial_{i}=\partial/\partial z_{i}$ and $\partial_{a}=(\partial_{0}, \partial_{1}, \partial_{a})=(\partial_{0}, \partial_{1}, \partial')=(\partial_{0}, \partial')$. $|z|=\max\{|z_{i}| \ ; \ 0 \leq i \leq n\}$. $N=\{1, 2, 3, \ldots\}$ and $Z^*=[0, 1, 2, \ldots]$. For a real number $a$, $[a]$ means the integral part of $a$. Let $K$ be a nonsingular complex hypersurface through $z=0$. We choose the coordinate so that $K=\{z_{0}=0\}$ to simplify the statements. In order to give the results we define firstly the characteristic indices $[\sigma_{i}]$ ($0 \leq i \leq p$) for a linear partial differential operator $L(z, \partial_{z})$ of order $m \geq 1$ and with the holomorphic coefficients in a neighbourhood of $z=0$, and secondly function spaces. The characteristic indices were introduced in [9] and [10]. We write $L(z, \partial_{z})$ in the following:
where \( L_k(z, \partial) \) is the homogeneous part of the order \( k \), \( A_{k, j}(z, \partial') \neq 0 \) if \( L_k(z, \partial) \neq 0 \), and otherwise we put \( s_k = +\infty \) by expanding \( A_{k, j}(z, \partial') \) with respect to \( z_0 \). We put conventionally \( j(k, l) = +\infty \) if \( A_{k, j}(z, \partial') = 0 \). We have

\[
L_k(z, \partial) = \sum_{i=0}^{m} z_0^{i+j(k, l)} a_{k, j}(z, \partial')(\partial_0)^{k-l},
\]

where \( d_k = \min \{ d_k = l+j(k, l) \} \), and \( d_k = +\infty \) if \( L_k(z, \partial') \equiv 0 \). If \( d_k < +\infty \), put

\[
\begin{align*}
\{ l_k &= \max \{ l \mid l+j(k, l) = d_k \}, \quad a_{k, j}(z, \partial') \neq 0 \}, \\
j_k &= d_k - l_k.
\end{align*}
\]

Obviously \( l_k \geq s_k \). When \( l+j(k, l) > d_k \), we do not have to expand \( A_{k, j}(z, \partial) \) with respect to \( z_0 \) up to \( j(k, l) \). Then we have

\[
A_{k, j}(z, \partial) = z_0^{l+j(k, l)} a_{k, j}(z, \partial)(\partial_0)^{k-l},
\]

and use this expression in (1.2). So, when \( l+j(k, l) > d_k \), we put \( j(k, l) = j'(k, l) \) and \( a_{k, j}(z, \partial') = a_{k, j}(z, \partial') \). Let us define the characteristic indices \( \{ \sigma_i \mid 0 \leq i \leq p \} \). Consider the set \( A = \{(k, d_k) \in \mathbb{R}^2 \, ; \, 0 \leq k \leq m, \, d_k \neq +\infty \} \) and its convex hull \( \tilde{A} \). Let \( \Sigma \) be the lower convex part of the boundary of \( \tilde{A} \). In general \( \Sigma \) consists of segments \( \Sigma(i) \) (\( 1 \leq i \leq \rho' \)) and let \( \Delta \) be the set of vertices of \( \Sigma \), \( \Delta = \{(k_i, d_{k_i}) \in \mathbb{R}^2 \, ; \, i = 0, 1, \ldots, \rho' \} \), \( m = k_0 > k_1 > \cdots > k_{\rho'} \geq 0 \) (see Fig. 1.1). We define as in [9] and [10],

\[
\sigma_i = \max \{ 1, \, d_{k_i-1} - d_{k_i} / (k_{i-1} - k_i) \}.
\]

Then there is a \( p \in \mathbb{N} \), \( p \leq \rho' + 1 \), such that \( \sigma_1 > \sigma_2 > \cdots > \sigma_{\rho'} > 1 = \sigma_p \), and we put \( \sigma_0 = +\infty \). If \( \Sigma \) consists of one point \( (m, d_m) \), put \( \sigma_i = 1 \).

We put \( \Sigma(0) = \{(m, d_m) \in \mathbb{R}^2 \, ; \, d_m, 1 \neq +\infty \} \). We note that
Definition 1.1. We call \( \{a_i; 0 \leq i \leq p\} \) the characteristic indices of the surface \( K \) for \( L(z, \partial_z) \).

Let us define function spaces. For a set \( A \subset \mathbb{C}^N \), \( \tilde{A} \) is the universal covering space of \( A \). \( \mathcal{O}(A) \) (resp. \( \mathcal{O}(\tilde{A}) \)) is the set of all holomorphic functions on \( A \) (resp. \( \tilde{A} \)). \( \mathcal{O}(\tilde{A}) \) contains multi-valued holomorphic functions on \( A \).

Definition 1.2. For \( \kappa, h > 0 \), \( \mathcal{O}_{\kappa, h}(Q(a, b)) \) is the set of all \( f(z) \in \mathcal{O}(Q(a, b)) \) such that for any \( a' < b' < b \) and any \( D \in \Omega' \)

\[
|f(z)| \leq A \exp(h|z_0|^{-\kappa}) \quad \text{in} \quad Q((a', b'), D)
\]

for a constant \( A = A(a', b', D) \). We put \( \mathcal{O}_{\kappa, h}(Q(a, b)) = \bigcap_{h > 0} \mathcal{O}_{\kappa, h}(Q(a, b)) \).

\( f(z) \in \mathcal{O}_{\kappa}(Q(a, b)) \) if and only if for any \( a' < b' < b \), any \( \varepsilon > 0 \) and any \( D \in \Omega' \)

\[
|f(z)| \leq A_{\varepsilon, a', b', \delta} \exp(\varepsilon|z_0|^{-\kappa}) \quad \text{in} \quad Q((a', b'), D).
\]

Function spaces introduced in the following are characterized by the behaviour of functions near \( K = \{z_0 = 0\} \).

Definition 1.3. \( \text{Asy}_{\kappa}(Q(a, b)) \), \( 0 < \kappa \leq +\infty \), is the class of all \( f(z) \in \mathcal{O}(Q(a, b)) \) having the asymptotic expansion of the following form as \( z_0 \to 0 \): for any \( N \geq 1 \)

\[
|f(z) - \sum_{k=0}^{N-1} a_k(z')z_0^k| \leq AB^N(N/\kappa + 1)|z_0|^N
\]
in any \( Q((a', b'), D) \) (\( a < a' < b', D \in \Omega' \)), where \( a_k(z') \in \mathcal{O}(\Omega') \), \( A \) and \( B \) are constants depending on \( Q(a', b', D) \). \( f(z) \in \text{Asy}_{\kappa}(Q(a, b)) \) is said to have the \( \kappa \)-asymptotic expansion in \( Q(a, b) \).

We note that \( f(z) \in \text{Asy}_{1+\infty}(Q(a, b)) \) means \( f(z) \in \mathcal{O}(Q) \).

Definition 1.4. (1) \( \mathcal{R}_\kappa \text{-asym}(Q(a, b)) \), \( 0 < \kappa \leq +\infty \), is the class of all \( f(z) \in \mathcal{O}(Q(a, b)) \) having the following asymptotic expansion in the form with polar and logarithmic terms as \( z_0 \to 0 \): for any \( N \geq 1 \)
\begin{equation}
|f(z) - \sum_{k=0}^{N-1} a_k(z') z^k| \leq AB^N \Gamma(N/k+1) |z_0|^N |\log z_0|, \quad \text{and}
\end{equation}

\begin{equation}
|f(z) - \sum_{k=0}^{N-1} a_k(z') z^k| \leq AB^N \Gamma(N/k+1) |z_0|^N
\end{equation}

hold in any $Q((a', b'), D) \ (a < a' < b' < b, D \in \mathcal{Q})$, where $H \in \mathbb{Z}_+$ and $a_k(z'), b_k(z') \in \mathcal{O}(Q')$. $A$ and $B$ are constants depending on $a'$, $b'$ and $D$.

(2) $\mathcal{R}(Q-K)$ is the set of all $f(z) \in \mathcal{O}(Q-K)$ having at most polar or logarithmic singularities on $K$, that is, $f(z) = a(z) \log z_0 + b(z)/z^\gamma$, $a(z), b(z) \in \mathcal{O}(Q), H \in \mathbb{Z}_+$. We note that if $f(z) \in \mathcal{R}-\text{asy}_{i=1}^{(Q(a, b))}$ and $b-a \leq \pi/k$, then there are $a(z), b(z) \in \text{Asy}_{i=1}^{(Q(a, b))}$ such that $f(z) = a(z) \log z_0 + b(z)/z^\gamma$ (see Proposition 2.1). We have $\mathcal{R}-\text{asy}_{i=0}^{(Q(a, b))} = \mathcal{R}(Q-K)$.

Now let us state the main results.

**Theorem 1.5.** Suppose that $L(z, \partial_z)$ satisfies the conditions
\begin{equation}
(1.11) \quad (a) \sigma_1 > 1, \quad (b) \ d_{k-p-1} = 0, \quad (c) \ d_{k_1} = s_{k_1} \quad \text{for} \ 0 \leq i \leq p-2.
\end{equation}

Let $\theta_0$ be an arbitrary positive constant and $u(z) \in \mathcal{O}(Q(\theta_0))$ be a solution of
\begin{equation}
(1.12) \quad L(z, \partial_z) u(z) = f(z) \in \text{Asy}_{i=1}^{(Q(\theta_0))},
\end{equation}
where $0 < \kappa \leq \gamma = \sigma_{p-1} - 1$. If $u(z) \in \mathcal{O}_{i=1}^{(Q(\theta_0))}$, then $u(z) \in \text{Asy}_{i=1}^{(Q(\theta_0))}$.

**Corollary 1.6.** In Theorem 1.5, if $f(z) \in \mathcal{O}(Q)$ and $\theta_0 > \pi/(2\gamma) + \pi$, then $u(z) \in \mathcal{O}(Q)$.

Corollary follows from Proposition 2.9.

**Theorem 1.7.** Suppose that $L(z, \partial_z)$ satisfies the conditions (1.11)-(a), (b), (c).

Let $\theta_0$ be an arbitrary positive constant and $u(z) \in \mathcal{O}(Q(\theta_0))$ be a solution of
\begin{equation}
(1.13) \quad L(z, \partial_z) u(z) = f(z) \in \mathcal{R}-\text{asy}_{i=1}^{(Q(\theta_0))},
\end{equation}
where $0 < \kappa \leq \gamma = \sigma_{p-1} - 1$. If $u(z) \in \mathcal{O}_{i=1}^{(Q(\theta_0))}$, then $u(z) \in \mathcal{R}-\text{asy}_{i=1}^{(Q(\theta_0))}$.

**Corollary 1.8.** In Theorem 1.7, if $f(z) \in \mathcal{R}(Q-K)$ and $\theta_0 > \pi/(2\gamma) + 2\pi$, then $u(z) \in \mathcal{R}(Q-K)$.

Corollary 1.8 also follows from Proposition 2.9.

**Remark 1.9.** Suppose that $L(z, \partial_z)$ satisfies (1.11) then $d_{k_1} = s_{k_1} = l_{k_1}$ and
The condition (1.11)-(a) means that $K = \{z_0 = 0\}$ is a irregular characteristic surface defined in [9], and the conditions (1.11)-(b), (c) mean that the $r$-th localization of $L(z, \partial_x)$ on $K$ is $a_{k_1, \cdots, k_t}(0, z', \partial' )$ and the $(p-1)$-th localization on $K$ is a function $a_{s_{p-1}, s}(0, z')$. It follows from (1.5) that there are $r \geq 0$ and $\xi' \neq 0$ such that

$$(1.14) \quad \prod_{t=0}^{p-1} a_{k_1, \cdots, k_t}(0, z', \xi') \neq 0 \quad \text{for } |z'| = r.$$ 

Many of the results in this paper were announced in [11], where (1.11)-(a), (b), and instead of (1.11)-(c), only $d_m = s_m$ are assumed. The author thinks that the assertions in Theorem 1.5 and others hold under these weaker conditions, but they can not be shown by the method in this paper.

We give other results in the present paper which are used to prove the preceding Theorems. In the following the coordinate $(w, z, t)$ means a point in $C^1 \times C^{n+1} \times C^{n+1}$. Put

$$(1.15) \quad W_0 = \{(w, z, t); |w| > A|f_0|, |z| \leq r_1, |t_0| \leq r_2, r_2 \leq |t_i| \leq r_3 \quad (i \geq 1)\},$$

where $0 < \xi < \pi/2$ and $0 < r_1 < r_2 < r_3$.

**Definition 1.10.** $K(W_0)$ is the set of all $K(w, z, t) \in C(W_0)$ such that: for any fixed $w$, $K(w, z, t)$ is single valued holomorphic in $(z, t)$, and for any fixed $(z, t)$ it is holomorphic on the universal covering space of $\{w \in C^1; (\sin \delta)|t_0| < |w| < +\infty\}$.

Now let us define integral operators, using $K(w, z, t) \in C(W_0)$. Put $Q = \{t \in C^{N+1}; |t| \leq r_3\}$ and $U = \{z \in C^{n+1}; |z| \leq r_1\}$. Firstly we define a path $T(a, b)$ in $t$-space, $0 < b-a \leq 2\pi$, $T(a, b) = T_0(a, b) \times T' \subset C^1 \times C^N$. $T_0(a, b) = T_0(a, b) + T_1(a, b) + T_2(a, b)$ is a path in $t_0$-space, where $T_0(a, b) = \{t_0 = (1-s_1)|r_3 + s_1|e^{i\alpha}; 0 \leq s_1 \leq 1\}$, $T_1(a, b) = \{t_0 = \eta e^{i\phi}; a \leq \phi \leq b\}$ and $T_2(a, b) = \{t_0 = (s_2 + (1-s_2)|r_3|e^{i\alpha}; 0 \leq s_2 \leq 1\}$ (see Fig. 1.2.). $T'$ is the product of paths $\{t_i = r_s |e^{i\alpha}; 0 \leq \phi \leq 2\pi\}$ ($i = 1, 2, \cdots, N$) in $C^N$. In the later sections we use the path $T$ when $N = n$ or $N = n - 1$. When $N = n - 1$, we use the notation $t = (t_0, t_2, \cdots, t_n) = (t_0, t^*)$ and $T'$ is denoted by $T^*$.

![Fig. 1.2](image)

Let us define for $f(z) \in C(Q(a, b))$, $b - a > 2\delta$, 

$$j(k_t, l_{k_t}) = 0 \text{ for } 0 \leq i \leq p - 1.$$
where $T=T_0(a', b')$ with $a < a' < b' < b$ and $2\delta < b' - a' \leq 2\pi$. We will show in § 5 that if $f(z) \in \mathcal{O}(\mathcal{Q}(a, b))$, $b - a > 2\delta$, then $(Kf)(z) \in \mathcal{O}(U(a + \delta, b - \delta))$ for a neighbourhood $U$ of $z=0$.

In order to show the preceding theorems we need the following Theorems 1.11 and 1.13.

**Theorem 1.11.** Suppose that $L(z, \partial_z)$ satisfies the conditions

\[ (1.17) \quad (a) \quad \sigma > 1, \quad (b) \quad d_{k_p - 1} = 0, \quad (c) \quad a_{k_p - 1, q}(0) \neq 0. \]

Put $\gamma = \sigma - 1$ and $\alpha = (\sigma - 1)/\sigma$. For given $\phi \in R$ and any small $\delta > 0$, there are $G(\phi; w, z, t) = G_{\phi}(\phi; w, z, t) K(W) \in K(W)$ and $G_{\phi}(\phi; w, z, t) = G_{\phi}(\phi; w, z, t) K(W)$ with the following $(1)-(5)$.

1. There is a neighbourhood $U$ of $z=0$ such that $(G^\phi f)(z) \in \mathcal{O}(U(a + \delta, b - \delta))$ and

\[ (1.18) \quad L(z, \partial_z)(G^\phi f)(z) = f(z) + (G^\phi f)(z) + a \text{ holomorphic function on } U. \]

2. Let $f(z) \in \mathcal{O}(1, h(\mathcal{Q}(a, b))$, where $\phi - \pi/(2\alpha) + \pi/2 < a < b < \phi + \pi/(2\alpha) + 3\pi/2$ and $b - a > \pi + 2\delta$. Then for any $\varepsilon > \delta$ there is a constant $c = c(\varepsilon) > 0$ such that $(G^\phi f)(z) \in \mathcal{O}(U(a + \varepsilon, b - \varepsilon))$.

3. Suppose $\phi^* < \phi^\sigma = 0 < \alpha \delta < (\pi - \alpha|\phi^\sigma - \phi^\sigma|)/2$. Let $f(z) \in \mathcal{O}(1, h(\mathcal{Q}(a, b))$, where $\phi^\sigma - \pi/(2\alpha) + \pi/2 < a < b < \phi^\sigma + \pi/(2\alpha) + 3\pi/2$ and $b - a > \pi + 2\delta$. Then there is an $h_0$ such that if $0 < h < h_0$, $(G^\phi f)(z) - (G^\phi f)(z) \in \mathcal{O}(U(a + \delta_0, b - \delta_0))$.

4. Let $\kappa > 0$ be arbitrary. Let $f(z) \in \mathcal{O}(1, h(\mathcal{Q}(a, b))$, where $\phi < a < b < \phi + 2\pi$ and $b - a > 2\delta$. Then $(G^\phi f)(z) \in \mathcal{O}(1, h(\mathcal{Q}(a, b))$.

5. Let $f(z) \in \mathcal{O}(1, h(\mathcal{Q}(a, b))$. Suppose that one of the following conditions holds:

1. $\phi - \pi/(2\alpha) + \pi/2 < a < b < \phi + \pi/(2\alpha) + 3\pi/2$ and $b - a > \pi + 2\delta$,
2. $\phi - \pi/(2\alpha) + 3\pi/2 < a < b < \phi + \pi/(2\alpha) + \pi/2$ and $b - a > 2\delta$.

Then there is an $h_1$ such that, if $0 < h < h_1$, $(G^\phi f)(z) \in \mathcal{O}(1, h(\mathcal{Q}(a, b))$.

**Remark 1.12.** Suppose $L(z, \partial_z)$ satisfies the conditions $(1.11)-(a)$, (b), which are the same as $(1.17)-(a)$, (b). Then it is written in the form

\[ (1.19) \quad L(z, \partial_z) = a_{k_p - 1, q}(z) \partial_z^{k_p - 1} + \sum_{(k, l) \in \mathcal{S}_{k_p - 1}} z^{(k, l)} a_{k, l}(z) \partial_z^{k - l}, \]

where $k - d_{k, l} = k - (l + j(k, l)) < k_{p - 1}$ for $(k, l) \in (k_{p - 1}, 0)$. So, if $(1.17)-(c)$ is valid, then for a given formal power series $f(z)$ of $z_0$, $f(z) = \sum_{n=0}^{\infty} f_n(z') z'/n!$, $f_n(z) \in \mathcal{O}(\mathcal{Q})$, there is a formal power series $u(z) = \sum_{n=0}^{\infty} u_n(z') z'/n!$, $u_n(z') \in \mathcal{O}(\mathcal{Q})$, such that $L(z, \partial_z) u(z) = f(z)$ as a formal power series of $z_0$. 

**Solutions with Singularities 69**
We have the following which we apply to the proof of Theorem 1.7.

**Theorem 1.13.** Suppose that $L(z, \partial_z)$ satisfies the condition (1.17) and put $\gamma = \sigma_{p-1} - 1$. Let $f(z) \in \text{Asy}_\text{re}(U(\theta))$ with $0 < \theta \leq \pi / 2\kappa$ and $0 < \varepsilon \leq \gamma$. Then there is a $b(z) \in \mathbb{R} - \text{Asy}_\text{re}(U(\theta))$ such that $L(z, \partial_z) b(z) - f(z) \log z \in \text{Asy}_\text{re}(U(\theta))$, where $U$ is a neighbourhood of $z = 0$.

At the end of this section we show an example. Let $L(z, \partial_z)$ be an operator of the form

$$(1.20) \quad L(z, \partial_z) = (\partial_z)^k + A_1(z, \partial') (\partial_z)^{m_1} + A_m(z, \partial'),$$

where $\text{ord} A_1(z, \partial') = l \geq 1$, and $\text{ord} A_m(z, \partial') = m_2$. We assume that $k < m_1 < m_2$, $(\text{P.S.} A_1)(z, \xi') |_{\xi' = 0} \neq 0$ and $(\text{P.S.} A_m)(z, \xi') |_{\xi' = 0} \neq 0$, where $(\text{P.S.} A)(z, \xi)$ means the principal symbol of $A(z, \partial')$.

Case (1) $(m_2 - l)/(m_2 - m_1) \leq l/(m_1 - k)$. We have $\sigma_1 = m_2/(m_2 - k) > 1$, $\sigma_2 = 1$, $p = 2$ and $\gamma = \sigma_1 - 1$. The conditions (1.11)-(a), (b), (c) are satisfied.

Case (2) $(m_2 - l)/(m_2 - m_1) > l/(m_1 - k)$. We have $\sigma_1 = (m_2 - l)/(m_2 - m_1)$, $\sigma_2 = l/(m_1 - k)$, $\sigma_3 = 1$, $p = 3$ and $\gamma = \sigma_3 - 1$. The conditions (1.11)-(a), (b), (c) are satisfied.

Case (3) $(m_2 - l)/(m_2 - m_1) > l/(m_1 - k)$. We have $\sigma_1 = (m_2 - l)/(m_2 - m_1)$, $\sigma_2 = 1$, $p = 2$, $d_{k+1} = l \geq 1$. So (1.11)-(b) does not hold.

Case (4) $1 \geq (m_2 - l)/(m_2 - m_1) \geq l/(m_1 - k)$. We have $\sigma_1 = 1$ and $d_{k+1} = m_2$. Neither (1.11)-(a) nor (b) is valid.

According to the classification of characteristic surfaces in [9], in Cases (1)-(3) $K = \{z_0 = 0\}$ is irregular characteristic and in Case (4) $K = \{z_0 = 0\}$ is regular characteristic.

### §2. Function Spaces

In §1 we introduced some classes of holomorphic functions. In the present section we give some properties of them, which are used to show Theorems and Corollaries stated in §1. Some of them were given in [12] and we refer the proofs of them to it. In the definitions of function spaces in §1, $z$ means the $(n+1)$-variables, $z = (z_0, z') \in \mathbb{C}^{n+1}$, but the variable $z_0$ is important and other variables $z'$ are not. Hence $z$ or $t$ means one complex variable in §2 except Proposition 2.8.

Firstly we study functions with asymptotic expansions on the half axis. Let $u(z)$ be a function defined on the line $\{z; \arg z = \varphi, 0 \leq |z| < A\}$ having the $\kappa$-asymptotic expansion,

$$u(z) \sim \sum_{k=0}^{\infty} c_k z^k \quad (2.1)$$

that is, if for any $N \geq 1$
We may assume \( \varphi = 0 \). We have from (2.2)

\[
|c_k| \leq AR^{-k} \Gamma(k/\kappa + 1).
\]

Conversely, let \( \{c_k\} \) \((k=0, 1, \ldots)\) be a sequence satisfying (2.3). Put

\[
g(t) = \sum_{k=0}^{\infty} \frac{c_k t^k}{\Gamma(k/\kappa + 1)} \quad (t \in \mathbb{C}^+),
\]

which is holomorphic in \( \{t \in \mathbb{C}^+ ; |t| < R\} \) and \( |g(t)| \leq A(1-|t/R|)^{-1} \). Put

\[
v(z) = z^{-\mu} \int_0^\infty \exp(-z^{-\mu}t)g(t^{1/\kappa})\,dt, \quad 0 < c^{1/\kappa} < R,
\]

which depends on \( c \). Then we have

**Proposition 2.1.**

1. \( v(z) \in \mathcal{O}(C^1 - \{0\}) \).
2. \( v(z) \) has the \( \kappa \)-asymptotic expansion as \( z \to 0 \) in \( \{z ; |\arg z| < \pi/2\kappa\} \), that is, there is an \( A(c) \) such that for any \( N \)

\[
|v(z) - \sum_{k=0}^{N-1} c_k z^k| \leq A(c)c^{-N/\kappa}(\cos(\kappa\theta'))^{-N/\kappa-1} \Gamma(N/\kappa + 1)|z|^N
\]

holds in \( \{z ; |\arg z| < \theta'\} \) for any \( \theta' \) with \( 0 < \theta' < \pi/2\kappa \).

Set \( w(z) = u(z) - v(z) \). By Proposition 2.1, \( u(z) \) and \( v(z) \) have the same asymptotic expansion on the positive real axis as \( z \to 0 \). Hence \( w(z) \sim 0 \) as \( z \to 0 \) on the positive real axis. More precisely we have

**Lemma 2.2.**

\[
|w(x)| \leq A c^{-n/\kappa} \Gamma(n/\kappa + 1)|x|^n \quad \text{for each } n, \quad |w(x)| \leq C(c x^{-\gamma})^{1/\kappa} \exp(-c x^{-\gamma}) \quad \text{for } 0 \leq x \leq 1, \text{ where } A \text{ and } C \text{ depend on } c.
\]

The proofs of Proposition 2.1 and Lemma 2.2 were in [12]. We'll define the \( \kappa \)-Laplace transform and investigate relations between functions with the \( \kappa \)-asymptotic expansion and their \( \kappa \)-Laplace transforms. Let \( \chi(x) \) be a continuous function on \((0, A) \) \((A > 0)\) with \( |\chi(x)| \leq \mathcal{C} \exp(h \, |x|^{-\gamma}) \) \((\kappa > 0)\). We define the \( \kappa \)-Laplace transform \( \hat{\chi}(\xi) \) of \( \chi(x) \) by

\[
(2.1) \quad \hat{\chi}(\xi) = \int_{-\infty}^{\infty} \exp(\xi x)\chi(x^{-1/\kappa})x^{-1}\,dx \quad (a > A^{-\gamma}),
\]

which is holomorphic in \( \{\xi ; \text{Re} \xi < -h\} \). \( \hat{\chi}(\xi) \) depends on \( a \), we may choose any \( a \) with \( a > A^{-\gamma} \) and fix it. The inversion formula is given by

\[
(2.8) \quad \chi(x) = \frac{1}{2\pi i} \int_{d-h}^{d+h} \exp(-\xi x^{-\gamma})\hat{\chi}(\xi)\,d\xi \quad (d < -h) \quad \text{for } 0 < x < a^{-1/\kappa}.
\]

Let \( \hat{u}(\xi) \) be the \( \kappa \)-Laplace transform of \( u(x) \) with the \( \kappa \)-asymptotic expansion (2.1). Since \( \hat{u}(\xi) = \hat{v}(\xi) + \hat{w}(\xi) \), \( v(z) \) being defined by (2.5), we study \( \hat{v}(\xi) \) and
Lemma 2.3. (1) \( \tilde{\omega}(\xi) \in \mathcal{O}(\xi; \text{Re } \xi < c) \).
(2) \( \tilde{\omega}(\xi) \in \mathcal{O}(\xi; \xi \in \mathbb{C}^1; \text{Re } \xi < 0) \). It has the holomorphic prolongation around \( \xi = 0 \) so that \( \tilde{\omega}(\xi) \in \mathcal{O}(\tilde{\mathcal{E}}_s), \mathcal{E}_s = \{ \xi \in \mathbb{C}^1; 0 < |\xi| < c \} \).
(3) \( |\tilde{\omega}(\xi)| \leq M_{r, \theta} |\log \xi| \) in \( \{ \xi; |\text{arg } \xi| < \theta, 0 < |\xi| < r \} \) for any \( \theta \) and \( 0 < r < c \).
(4) \( \tilde{\omega}(\xi) - \tilde{\omega}(\xi e^{i\pi}) / 2\pi i = g(\xi^{1/2}) \), where \( g(\xi) \) is defined by (2.4) and \( \xi^{1/2} = |\xi|^{1/2} e^{i(\text{arg } \xi)/2} \).

It follows from Lemma 2.2 that \( \tilde{\omega}(\xi) \in \mathcal{O}(\xi; \text{Re } \xi < c) \). We refer the proof of (2)-(4) to [12]. Thus we have

Proposition 2.4. Let \( u(x) \) be a function with the asymptotic expansion (2.1) on \([0, A]\). Then there is a constant \( c > 0 \) such that
(1) \( \tilde{u}(\xi) \) is holomorphic in \( \{ \xi; \text{Re } \xi < c, \xi \in [0, c) \} \),
(2) \( \tilde{u}(\xi) \) is holomorphically extensible onto \( \mathcal{E}_s = \{ \xi; 0 < |\xi| < c \} \) such that \( \tilde{u}(\xi) \in \mathcal{O}(\tilde{\mathcal{E}}_s) \),
\[
|\tilde{u}(\xi)| \leq M_{r, \theta} |\log \xi| \text{ in } \{ \xi; |\text{arg } \xi| < \theta, 0 < |\xi| < r \} \text{ (} 0 < r < c \text{)}
\]
for any \( \theta > 0 \) and \( \tilde{u}(\xi) - \tilde{u}(\xi e^{i\pi}) / 2\pi i = g(\xi^{1/2}) \).

Next we consider functions holomorphic in a sector \( \Omega(a, b), \Omega = \{ z; |z| < R \} \). In the sequel we only consider \( u(z) \in \mathcal{O}(\text{rel.}, \Omega(a, b)) \). We can define the \( \kappa \)-Laplace transform \( \tilde{u}(\xi) \) of \( u(z) \) by
\[
\tilde{u}(\xi) = \int_A^{\text{exp } i\varphi} \exp(\xi z) u(z^{-1/2}) z^{-1} dz \quad (a < -\varphi/\kappa < b),
\]
where \( |A| > R^{-\kappa} \) and \( a < -(\arg A)/\kappa < b \), \( \tilde{u}(\xi) \) depends on \( A \). We may choose any \( A \) satisfying the conditions and we fix it. \( \tilde{u}(\xi) \) is holomorphic on the set
\[
\mathcal{E}(h, a, b)
\]
\[
= \bigcup_{a < -\varphi < b} \{ \xi = |\xi| e^{i\varphi} \in \mathbb{C}^1; |\xi| \cos(\varphi + \varphi) < -h, |\varphi + \varphi - \pi| < \pi/2 \}.
\]

We have

Theorem 2.5. Let \( u(z) \in \mathcal{O}(\text{rel.}, \Omega(a, b)) \). Suppose that the \( \kappa \)-Laplace transform \( \tilde{u}(\xi) \in \mathcal{O}(\mathcal{E}(h, a, b)) \) is holomorphically prolonged to the punctured disk \( \tilde{\mathcal{E}}_s, \mathcal{E}_s = \{ 0 < |\xi| < c \} \), for some \( c > h \) so that
(1) for any \( \Phi > 0 \) \( |\tilde{u}(\xi)| \leq M_\Phi |\log \xi| \) in \( \{ \xi \in \tilde{\mathcal{E}}_s; |\text{arg } \xi - \pi| < \Phi \} \), and
(2) \( F(\xi) = \{ \tilde{u}(\xi) - \tilde{u}(\xi e^{i\pi}) / 2\pi i \} \) is a convergent power series of \( \xi^{1/2} \) at \( \xi = 0 \).
\[
F(\xi) = \sum_{n=0}^{\infty} c_n \xi^{n/2} / \Gamma(N/\kappa + 1).
\]

Then there is an \( h_0 = h_0(c) > 0 \) such that the following hold. If \( h < h_0 \), there are \( a' = a'(h) \) and \( b' = b'(h) \) \( \{ a < a' < b' < b \} \) such that \( u(z) \) has the \( \kappa \)-asymptotic
expansion (2.1) in $\Omega(a', b')$ and $\lim_{h \to 0} a'(h) = a$ and $\lim_{h \to 0} b'(h) = b$.

Proof. We may assume that $a = -\theta_0$ and $b = \theta_0$ ($\theta_0 > 0$). Firstly we note that there exists $0 < h < c$ such that if $0 < h < h_0$, $\Xi(h, -\theta_0, \theta_0) \cup \Xi = \{ \xi = |\xi| e^{i\phi} \; | \; \xi = 0, |\phi - \pi| < \theta_0 \}$ for some $\theta_0 = \theta_0(h) > \pi/2$ with $\lim_{h \to 0} \theta_0(h) = \kappa \theta_0 + \pi/2$. By the deformation of the integration path to the right half plane, the inverse $\kappa$-Laplace transform is given by

$$u(z) = \frac{z^{-\kappa}}{2\pi i} \left( \int_{\arg z = \pi/2} + \int_{c} \right) e^{i\xi} \exp \left( -\xi z^{-\kappa} \right) d\xi$$

for $z \in \Omega((\theta' - \pi/2)/\kappa)$ ($\pi/2 < \theta' \leq \pi$). From the assumption, $\hat{u}(\xi)$ has at most the logarithmic growth at $\xi = 0$. Hence, by deforming the integration path (see Fig. 2.1), we have for $z \in \Omega((\theta' - \pi/2)/\kappa)$ with $\pi/2 < \theta' < \theta_0'$ and $\theta' \leq \pi$,

$$u(z) = \frac{z^{-\kappa}}{2\pi i} \int_{\arg z = 0} \exp \left( -\xi z^{-\kappa} \right) d\xi$$

Here $F(\xi) = \hat{u}(\xi) - \hat{u}(\xi e^{i\pi/2})$ and

$$s_{\theta'}(z) = \frac{z^{-\kappa}}{2\pi i} \left( \int_{\arg z = 0} + \int_{c} \right) \exp \left( -\xi z^{-\kappa} \right) d\xi.$$

For $z$ with $|\arg z| < \pi/2\kappa$ we have the $\kappa$-asymptotic expansion

$$z^{-\kappa} \int_{0}^{c} \exp \left( -\xi z^{-\kappa} \right) F(\xi) d\xi \sim \sum_{k=0}^{\infty} c_k z^k$$

and

$$|s_{\theta'}(z)| \leq A_{\theta', \kappa} \exp \left( -c_\delta |z|^{-\kappa} \right), \quad c_\delta > 0,$$

in $\{ z : 0 < |z| < A', \pi/2 - \theta' + \delta < \kappa \arg z < -\pi/2 + \theta' - \delta \}$ for any $\delta > 0$. Hence, we have the $\kappa$-asymptotic expansion of $u(z)$

$$u(z) \sim \sum_{k=0}^{\infty} c_k z^k$$

in $\Omega((\theta' - \pi/2)/\kappa)$.

Moreover if follows from the rotation of $z$ and using the above method again
that \( u(z) \) has the \( \kappa \)-asymptotic expansion (2.18) in \( \Omega((\theta^* - \pi/2)/\kappa) \). Put \(-a'(h) = b'(h) = (\theta^* - \pi/2)/\kappa \) and as mentioned above \( \lim \theta^*(h) = \kappa \theta_0 + \pi/2 \). Hence \( \lim_{h \to 0} -a'(h) = \lim_{h \to 0} b'(h) = (\theta^* - \pi/2)/\kappa = \theta_0 \).

From Proposition 2.4 and Theorem 2.5 we have

**Corollary 2.6.** Let \( u(z) \in \mathcal{O}((\Omega(a, b)) \). Then \( u(z) \) has the \( \kappa \)-asymptotic expansion in \( \Omega(a, b) \), if and only if the \( \kappa \)-Laplace transform \( \hat{u}(\xi) \in \mathcal{O}(\xi; \kappa a - \pi/2 < \arg \xi < \kappa b + \pi/2) \) satisfies the following (1) and (2).

1. \( \hat{u}(\xi) \) has holomorphic extension onto \( \Xi = \{ \xi; 0 < |\xi| < c \} \) such that \( \hat{u}(\xi) \in \mathcal{O}(\Xi) \) and \( |u(\xi)| \leq M_\delta |\log \xi| \) on \( \{ \xi \in \Xi; \kappa a - \pi/2 + \delta < \arg \xi < \kappa b + \pi/2 - \delta \} \) for any \( \delta > 0 \).

2. \( F(\xi) = \{ u(\xi) - \hat{u}(\xi e^{2\pi i}) \}/(2\pi i) \) has the convergent power series of \( \xi^{1+\epsilon} \) at \( \xi = 0 \) such as (2.12).

**Remark 2.7.** Put

\[
(2.19) \quad \hat{U}_s(\xi) = \frac{1}{2\pi i} \int_{t=0}^{t=\infty} \frac{t^{b/\epsilon}}{s-t-\xi} dt.
\]

Then \( \hat{U}_s(\xi) = \hat{U}_* (\xi e^{2\pi i}) = \xi^{b/\epsilon} \) for \( |\xi| < r \). Define

\[
(2.20) \quad \hat{U}(\xi) = \Sigma_{k=0}^\infty c_k \hat{U}_s(\xi)/\Gamma(N/k+1).
\]

Then \( \hat{U}(\xi) = \hat{U}(\xi e^{2\pi i}) = \Sigma_{k=0}^\infty c_k \xi^{b/\epsilon} / \Gamma(N/k+1) \) and it is easy to show that \( \hat{U}(\xi) \) has at most logarithmic growth at \( \xi = 0 \). Suppose that conditions (1) and (2) in Corollary 2.6 hold. We have \( \hat{u}(\xi) = \hat{U}(\xi) - \hat{U}(\xi e^{2\pi i}) = \hat{u}(\xi e^{2\pi i}) \) and \( \hat{u}(\xi) - \hat{U}(\xi) \in \mathcal{O}(\Xi) \), where \( \Xi = \{ \xi; 0 < |\xi| < c \} \). Since \( \hat{u}(\xi) \) and \( \hat{U}(\xi) \) has at most logarithmic growth at \( \xi = 0 \), \( \hat{u}(\xi) - \hat{U}(\xi) \in \mathcal{O}(\Xi) \). Therefore the behaviour of \( \hat{u}(\xi) \) at \( \xi = 0 \) is characterized by \( \hat{U}(\xi) \).

In the next proposition \( z = (z_0, z') \in C^{n+1} \) and \( \Omega = \Omega_0 \times \Omega' \) is a polydisk with the center \( z = 0 \) in \( C^{n+1} \).

**Proposition 2.8.** Let \( u(z) \in \mathcal{O}(\Omega(a, b)) \) and \( D \) be a non empty open set in \( \Omega' \). Suppose that \( u(z) \) has the \( \kappa \)-asymptotic expansion with respect to \( z_0 \) as \( z_0 \to 0 \) on \( \Omega_0 \times D \), then \( u(z) \) has also the \( \kappa \)-asymptotic expansion in \( \Omega(a, b) \).

**Proof.** We may assume \( -a = b = \theta_0 \). We have \( \hat{u}(\xi, z') \in \mathcal{O}(Z_0^{\theta_0+\pi/\kappa} \times \Omega') \), where \( Z_0 = \{ \xi \in C^1; |\arg \xi - \pi < \theta_0 \} \). If \( z' \in D \), \( \hat{u}(\xi, z') \in \mathcal{O}(Z_0^{\infty} \times D') \). Hence, it follows from the theory of the extension of holomorphic functions of several complex variables that \( \hat{u}(\xi, z') \) is holomorphically extensible around \( \xi = 0 \) for \( z' \in \Omega' \); that is, \( \hat{u}(\xi, z') \in \mathcal{O}(Z^*), Z^* = \{ (\xi, z') \in C^1; 0 < |\xi| < c(|z'|) \} \) for some \( c(|z'|) > 0 \) (see [4]). We have \( F(\xi, z') = \{ \hat{u}(\xi, z') - \hat{u}(\xi e^{2\pi i}, z') \}/(2\pi i) = \hat{U}(\xi, z') - \hat{U}(\xi e^{2\pi i}, z') \).
SOLUTIONS WITH SINGULARITIES

\[ \sum_{k=0}^{n} c_k(x') \xi^{k/k+1} \] 

and

\[ u(\xi, x') - \hat{U}(\xi, x') \in O(|\xi| < c(|x'|)) \] 

as a function of \( \xi \), where \( \hat{U}(\xi, x') = \sum_{k=0}^{n} c_k(x') \xi^{k/k+1} \) is defined by (2.20) for \( u(\xi, x') \). Hence it follows from Remark 2.7 that the conditions (1) and (2) in Corollary 2.6 hold. So \( u(x) \) has the \( \kappa \)-asymptotic expansion with respect to \( z_0 \) in \( Q(a, b) \).

Proposition 2.9. (1) Let \( f(z) \in \text{Asy}_{(a)}(Q(a, b)) \). If \( b-a > \pi/\kappa + 2\pi \), then \( f(z) \in O(Q) \).

(2) Let \( f(z) \in \mathfrak{R} \text{Asy}_{(a)}(Q(a, b)) \). If \( b-a > \pi/\kappa + 4\pi \), then \( f(z) \in \mathfrak{R}(Q-K) \).

Proof. (1) Put \( F(z) = f(z) - f(z^e-x^e) \), \( z \in Q(a, b-2\pi) \). Then \( F(z) \sim 0 \). More precisely for any \( N \geq 1 \) we have

\[ |F(z)| \leq AB^N I(N/\kappa + 1)|z|^N \quad \text{in } Q(a', b'-2\pi) \quad (a < a' < b' < b). \]

Choose \( a' \) and \( b' \) such that \( b' - a' > -2\pi > \pi/\kappa \). From (2.21) we have \( |F(z)| \leq A \exp(-c|z_0|^{-s}) \) in \( Q(a', b'-2\pi) \) for some \( c > 0 \). Since \( (b' - 2\pi) - a' > \pi/\kappa \), \( F(z) \equiv 0 \). So \( f(z) \) is single valued on \( Q-K \) and bounded. Consequently \( f(z) \) is holomorphic in \( Q \).

(2) Put \( F(z) = f(z) - f(z^e-x^e) \), \( z \in Q(a, b-2\pi) \). Then \( F(z) \in \mathfrak{R} \text{Asy}_{(a)}(Q(a', b'-2\pi)) \). We can choose \( a' \) and \( b' \) such that \( (b' - 2\pi) - a' > \pi/\kappa + 2\pi \). Hence \( F(z) \) \( \in \mathfrak{R}(Q) \) by (1). Put \( g(z) = f(z) + (1/2\pi i) F(z) \log z_i \). Then \( g(z) - g(z^e-x^e) = F(z) - 1/(2\pi i) \{ F(z) \log z + 2\pi i - F(z) \log z_0 \} = 0 \). So \( g(z) \) is single valued in \( Q-K \). Since \( |g(z)| \leq A |z_0|^{-H} \) for some \( H \geq 0 \), \( \{z_0 = 0\} \) is at most a pole of \( g(z) \). Thus \( f(z) = g(z) - 1/(2\pi i) F(z) \log z_i \in \mathfrak{R}(Q-K) \).

As stated in §1, we have Corollary 1.6 (resp. 1.8) by Theorem 1.5 (resp. 1.7) and Proposition 2.9.

Proposition 2.10. Let \( u(z) \in \mathcal{O}_{(a^1, a)}(Q(a, b)) \). Suppose that there exist \( u_i(z) \in \mathcal{O}_{(a_i^1, a)}(Q(a, b)) \) \( (i = 1, 2, \cdots, l, \kappa < \kappa_1 < \kappa_2 < \cdots < \kappa_l) \) such that \( u(z) = \sum_{i=1}^{l} u_i(z) \) and each \( u_i(z) \) has the \( \kappa_i \)-asymptotic expansion on \( \{z ; \arg z = \varphi_i, \kappa \} \), \( \kappa < |\varphi| < b \). Further assume that there is a \( \varphi_0 \in (a, b) \) such that \( |\varphi_i - \varphi_0| < \pi/\kappa_i \). Then there is an \( h_0 > 0 \) such that, if \( 0 < h < h_0 \), \( u(z) \in \text{Asy}_{(a)}(Q(a', b')) \) for some \( a' = a'_{(h)} \) and \( b' = b'_{(h)} \) \( (a < a' < b' < b) \) satisfying \( \lim_{h \to 0} a'_{(h)} = a \) and \( \lim_{h \to 0} b'_{(h)} = b \).

Proof. By the rotation of \( z \), we may assume \( a < 0 < b \) and \( \varphi_0 = 0 \). We have

\[ u(\xi) = \int_A^{+2\pi e i} \exp(\xi z) u(z^{-1/\kappa}) z^{-1} dz \quad (A > R^-) \quad \text{arg } z = \varphi \]

which is holomorphic in \( \mathcal{E}(h, a, b) \) (see (2.11)). \( u(\xi) \) is represented in the form

\[ u(\xi) = \lim_{z_i \to 0} \lim_{z_i \to 0} \cdots \lim_{z_i \to 0} \sum_{i=1}^{l} \exp(\xi z_0) u(z^{-1/\kappa_i}) z^{-1} dz \]

where \( \rho_i = \kappa_i/\kappa > 1 \) and \( |\varphi| < \pi/2\rho_i \). Suppose \( |\xi - \pi| < \theta^* \), where \( \theta^* = \ldots \)
Since \( \kappa \rho_1 \) is small compared to \( \pi \), we have

\[
\frac{\pi}{2} - \kappa \rho_1 > 0.
\]

Since \( \kappa \rho_1 \) is small, by putting \( \phi = -\kappa \rho_1 \), we have

\[
\tilde{u}(\xi) = \int_{A} \exp(\xi z) u(z^{-1/\kappa}) z^{-1} dz
\]

\[
= \lim_{\xi \to 0} \lim_{\xi_1 \to 0} \cdots \lim_{\xi_{\ell-1} \to 0} \int_{A} \exp(\xi z - \sum_{1}^{\ell} \xi_{i} z^{\rho_i}) (\sum_{i=1}^{\ell} u_i(z^{-1/\kappa})) z^{-1} dz,
\]

\[
+ \lim_{\xi \to 0} \lim_{\xi_1 \to 0} \cdots \lim_{\xi_{\ell-1} \to 0} \int_{A} \exp(\xi z - \sum_{1}^{\ell} \xi_{i} z^{\rho_i}) u_i(z^{-1/\kappa}) z^{-1} dz
\]

\[
= \lim_{\xi \to 0} \lim_{\xi_1 \to 0} \cdots \lim_{\xi_{\ell-1} \to 0} \int_{A} \exp(\xi z - \sum_{1}^{\ell} \xi_{i} z^{\rho_i}) (\sum_{i=1}^{\ell} u_i(z^{-1/\kappa})) z^{-1} dz
\]

\[
+ \int_{A} \exp(\xi z) u_i(z^{-1/\kappa}) z^{-1} dz.
\]

Since \( \kappa \rho_{\ell-1} \) is small, we also have

\[
\lim_{\xi \to 0} \lim_{\xi_1 \to 0} \cdots \lim_{\xi_{\ell-1} \to 0} \int_{A} \exp(\xi z - \sum_{1}^{\ell} \xi_{i} z^{\rho_i}) (\sum_{i=1}^{\ell} u_i(z^{-1/\kappa})) z^{-1} dz
\]

\[
= \lim_{\xi \to 0} \lim_{\xi_1 \to 0} \cdots \lim_{\xi_{\ell-1} \to 0} \int_{A} \exp(\xi z - \sum_{1}^{\ell} \xi_{i} z^{\rho_i}) u_i(z^{-1/\kappa}) z^{-1} dz
\]

\[
= \lim_{\xi \to 0} \lim_{\xi_1 \to 0} \cdots \lim_{\xi_{\ell-1} \to 0} \int_{A} \exp(\xi z - \sum_{1}^{\ell} \xi_{i} z^{\rho_i}) (\sum_{i=1}^{\ell} u_i(z^{-1/\kappa})) z^{-1} dz
\]

\[
+ \int_{A} \exp(\xi z) u_i(z^{-1/\kappa}) z^{-1} dz.
\]

Repeating this argument, we have for \( \xi \) with \( |\arg \xi - \pi| < \theta^* \)

\[
\tilde{u}(\xi) = \sum_{1}^{\kappa} \tilde{u}_i(\xi), \quad \tilde{u}_i(\xi) = \sum_{1}^{\ell} \int_{A} \exp(\xi z) u_i(z^{-1/\kappa}) z^{-1} dz.
\]

By the assumption \( u_i(z) \) has the \( \kappa \)-asymptotic expansion on \( \{ z ; \arg z < \rho_i \} \).

Hence \( \tilde{u}_i(\xi) \in \mathcal{O}(\mathcal{E}_x) \), \( \mathcal{E}_x = \{ 0 < |\xi| < c \} \), for some \( c > 0 \) and (1) and (2) in Proposition 2.4 hold for each \( \tilde{u}_i(\xi) \). Hence \( \tilde{u}(\xi) \in \mathcal{O}(\mathcal{E}(h, a, b)) \) has a holomorphic prolongation to \( \{ \xi ; |\arg \xi - \pi| < \theta^* \} \cup \mathcal{E}_0 \). So the assumptions in Theorem 2.5 hold and the assertions follow.

We give a few propositions for the later sections. The next two mean that holomorphic functions with bounds in a sector are represented as a sum of those in wider sectors.

**Proposition 2.11.** Let \( u(z) \in \mathcal{O}(\omega(a, b)) \). Given \( h > 0 \), there are \( u_i(z) \in \mathcal{O}(\omega_{\rho_i, h}(U(a, b + 2\pi)) \) and \( u_i(z) \in \mathcal{O}(\omega_{\rho_i, h}(U(a - 2\pi, b)) \) such that \( u(z) = u_1(z) + u_2(z) \) in \( U(a, b) \), where \( U \) is a neighbourhood of \( z = 0 \).
Proof. We may assume that $a < 0 < b$. Given $h > 0$, define

$$U(z) = \exp(\frac{hz - x}{3}) \exp(\frac{-ht - x}{3}) \exp(-u(t)dt).$$

Then, by deforming the integration path, we can prolong $U(z)$ to the $U(a, b + 2\pi)$, $U = \{|z| < r\}$. We denote by $u_i(z)$ this extension, $U(z)$ is also considered to be a holomorphic function on $U(a - 2\pi, b)$, say $u_i(z)$. Then we have $u(z) = u_1(z) + u_2(z)$ on $U(a, b)$ and we can easily show $u_1(z) \in \mathcal{O}(U(a, b + 2\pi))$ and $u_2(z) \in \mathcal{O}(U(a - 2\pi, b))$.

We have by the same method as in Proposition 2.11.

**Proposition 2.12.** Let $u(z) \in \mathcal{O}(Q(a, b))$. Given $h' > h$, there are $u_1(z) \in \mathcal{O}(U(a, b + 2\pi))$ and $u_2(z) \in \mathcal{O}(U(a - 2\pi, b))$ such that $u(z) = u_1(z) + u_2(z)$ in $U(a, b)$, $U = \{|z| < r\}$.

We give a relation $\text{Asy}_{i+1}(Q(a, b))$ between $\mathcal{M} - \text{Asy}_{i+1}(Q(a, b))$.

**Proposition 2.13.** For $u(z) \in \text{Asy}_{i+1}(Q(a, b))$ there is a $\tilde{u}(z) \in \mathcal{M} - \text{Asy}_{i+1}(U(a, b))$, $U = \{|z| < r\}$, such that $\tilde{u}(z) - u(z) \log z \in \text{Asy}_{i+1}(U(a, b))$.

**Proof.** We may assume that $a = -b = \theta$. Define

$$\tilde{u}(z) = \int_0^r \frac{u(t)}{z-t} dt.$$

Then $\tilde{u}(z) \in \mathcal{O}(U(-\theta, \theta + 2\pi))$, $U = \{|z| < r\}$. Put $w(z) = \int_0^r \frac{u(t) - u(z)}{t - z} dt$. Then

$$w(z) = \int_0^r \frac{u(z)}{z-t} dt + w(z) = u(z)(\log z - \log (z-r)) + w(z).$$

We show $w(z) \in \text{Asy}_{i+1}(U(\theta))$. We have $w(z) = \int_0^r dt \int_0^1 u'(st + (1-s)x) ds$ and $w^{(n)}(z) = \int_0^r dt \int_0^1 (1-s)^n u^{(n+1)}(st + (1-s)x) ds$. Hence if $|\arg z| < \theta, \theta, \theta$

$$w^{(n)}(z) \leq AB^{n+1} \Gamma\left(\frac{n+1}{\kappa} + 1\right)(n+1) \int_0^r dt \int_0^1 (1-s)^n ds$$

$$\leq AB^{n+1} \Gamma\left(\frac{n+1}{\kappa} + 1\right) n! ,$$

which means $w(z) \in \text{Asy}_{i+1}(U(\theta))$. Hence $\tilde{u}(z) - u(z) \log z \in \text{Asy}_{i+1}(U(a, b))$. 
§ 3. Integro-differential Operators Derived from $L(z, \partial_z)$

In order to show Theorems in § 1 we need integro-differential operators $\mathcal{L}_\alpha(z, \lambda, \zeta, \partial_\zeta, \lambda t_0 - \lambda \partial_j)$ $(0 < \alpha < 1)$ containing an integral operator $\partial_\zeta^{-1}$, where $z \in \mathbb{C}^{n+1}$ and $\lambda, \zeta, t_0 \in \mathbb{C}^*$. $\mathcal{L}_\alpha = \mathcal{L}_a(z, \lambda, \zeta, \partial_\zeta, \lambda t_0 - \lambda \partial_j)$ is derived from $L(z, \partial_z)$ in (1.1) as follows: Let $0 < \alpha < 1$. $L(z, \partial_z)$ is the sum of $L_{k,i}(z, \partial_z) = z_0^a a_{k,i}(z, \partial \zeta) \partial_\zeta^{-1} (j = j(k, l), s_k \leq t \leq m, 0 \leq k \leq m)$ (see (1.2)). We correspond $\mathcal{L}_{a,k,i} = \mathcal{L}_{a,k,i}(z, \lambda, \zeta, \partial_\zeta, \lambda t_0 - \lambda \partial_j)$ to each $L_{k,i}(z, \partial_z)$,

\begin{align}
\mathcal{L}_{a,k,i} &= \left( \lambda^{-1+\alpha} (\alpha \zeta + (\lambda t_0 - \lambda \partial_j) \partial_\zeta) \right)^t \left( \lambda^{a+1} a_{k,i}(z, \partial \zeta) \right) \left( \lambda^a \partial_\zeta + \lambda \right)^{h-i}.
\end{align}

Namely we get $\mathcal{L}_{a,k,i}$ from $L_{k,i}(z, \partial_z)$ by the following replacements:

\begin{align}
z_0 &\rightarrow \lambda^{-1+\alpha} (\alpha \zeta + (\lambda t_0 - \lambda \partial_j) \partial_\zeta), \\
\partial' &\rightarrow \lambda \partial \zeta \partial_\zeta^{-1}, \\
\partial_\zeta &\rightarrow \lambda \partial_\zeta \partial_\zeta^{-1} + \lambda,
\end{align}

but the variable $z_0$ in $a_{k,i}(z, \partial')$ is not replaced. Define

\begin{align}
\mathcal{L}_a = \mathcal{L}_a(z, \lambda, \zeta, \partial_\zeta, \lambda t_0 - \lambda \partial_j) = \sum_{k=0}^{m_k} \sum_{l=0}^{m_l} \mathcal{L}_{a,k,i}.
\end{align}

Now we define $\partial_\zeta^{-1}$ in $\mathcal{L}_a$. In order to do so we introduce a sequence of auxiliary functions $\{f_j(\zeta)\}$ ($j \in \mathbb{Z}$) used in [1]:

\begin{align}
f_j(\zeta) &= \frac{\zeta^j}{(2\pi i)^{j}} \left\{ \log \zeta - \left( 1 + \frac{1}{2} + \cdots + \frac{1}{j} \right) \right\}, \\
f_0(\zeta) &= \frac{1}{(2\pi i)} \log \zeta, \\
f_1(\zeta) &= \frac{(-1)^{j+1}}{2\pi i} (-j-1)! \zeta^j, \\
f_j(\zeta) &= \frac{1}{(2\pi i)^j} \left\{ \log \zeta - \left( 1 + \frac{1}{2} + \cdots + \frac{1}{j} \right) \right\}.
\end{align}

It is easy to show the next lemma.

**Lemma 3.1.** The following identities hold:

\begin{align}
\frac{d}{d\zeta} f_j(\zeta) &= f_{j-1}(\zeta), \\
\zeta f_j(\zeta) &= (j+1) f_{j+1}(\zeta) + a \text{ polynomial of } \zeta.
\end{align}

By considering Lemma 3.1, we define

\begin{align}
\partial_\zeta^{-1} f_{j-1}(\zeta+c) &= f_j(\zeta+c),
\end{align}

where $c$ does not depend on $\zeta$. By (3.6), we have

\begin{align}
\zeta f_j(\zeta+c) &= (j+1) f_{j+1}(\zeta+c) + a f_j(\zeta+c) \pmod{\text{polynomials of } \zeta}.
\end{align}

All the calculations with respect to $\zeta$ will be performed by the relations (3.5)-(3.8). Polynomials of $\zeta$ are neglected in all the calculations below. It will turn out that they make no contribution to the integration on the closed
paths in $\zeta$-space. The notation $\equiv$ means modulo polynomials of $\zeta$ in § 3.

Now we define the operation of $\mathcal{L}_a = \mathcal{L}_a(z, \lambda, \zeta, \partial_z, \partial_z, \lambda \partial_z - \lambda \partial_{\lambda})$ to a function $V(z, t, \lambda, \zeta, \tau)$ of the form

\[ V(z, t, \lambda, \zeta, \tau) = \sum_{n=0}^{+\infty} \nu_n(z, t, \lambda, \tau)f_n(\zeta + \tau z). \]

We prepare several lemmas for this operation. $\nu(z, t, \lambda, \tau)$ in Lemmas 3.2–3.4 and Proposition 3.5 is holomorphic in some domain.

**Lemma 3.2.**

\[ (\lambda^{-1+s} \partial_z \partial_z^{-1} + 1)^s \nu(z, t, \lambda, \tau) f_n(\zeta + \tau z) \]

\[ \equiv \sum_{\tau = 0}^{s} \binom{s}{\tau} \lambda^{(-1+s)\tau} \partial_0^{\tau} \nu(z, t, \lambda, \tau) f_{n+\tau}(\zeta + \tau z). \]

**Lemma 3.3.** There are linear partial differential operators $a_{k, t, s}(z, \partial') (0 \leq s \leq t)$ with ord. $a_{k, t, s}(z, \partial') \leq s$ such that

\[ a_{k, t, s}(z, \partial' \partial_z^{-1}) \nu(z, t, \lambda, \tau) f_n(\zeta + \tau z) \]

\[ \equiv \sum_{s=0}^{t} \binom{t}{s} a_{k, t, s}(z, \partial') \nu(z, t, \lambda, \tau) f_{n+s}(\zeta + \tau z), \]

where $a_{k, t, s}(z, \partial') = a_{k, t}(z, \zeta') | \zeta' = \xi = (1, 0, 0)$.

Lemma 3.2 follows from the binomial theorem and the proof of Lemma 3.3 is easy.

**Lemma 3.4.** The following identity holds:

\[ (\lambda^{-1+s}(\alpha \zeta + (\lambda t_0 - \lambda \partial_z) \partial_z^{-1}) )^s \nu(z, t, \lambda, \tau) f_n(\zeta + \tau z) \equiv \lambda^{(-1+s)\alpha} \{(\lambda t_0 - \lambda \partial_z) \partial_z^{-1} \nu(z, t, \lambda, \tau) f_n(\zeta + \tau z) \}. \]

Here $P(l, n, \lambda t_0 - \lambda \partial_z) = I$ and $P(l, n, \lambda t_0 - \lambda \partial_z) = \sum_{s=0}^{l} p_{k, s}(n)(\lambda t_0 - \lambda \partial_z)^s$, where constants $p_{k, s}(n) (0 \leq k \leq s, 0 \leq s \leq l)$ satisfy for constants $A$ and $B$

\[ | p_{k, s}(n) | \leq AB^l(|n| + |j| + 1)^{s-k}, \quad 0 \leq k \leq s \leq j. \]

**Proof.** The identity (3.11) is obvious for $j=0$. We have by (3.8)

\[ \lambda^{(-1+s)(\alpha \zeta + (\lambda t_0 - \lambda \partial_z) \partial_z^{-1})} \nu(z, t, \lambda, \tau) f_n(\zeta + \tau z) \]

\[ \equiv \lambda^{(-1+s)} \{(\alpha \zeta + (\lambda t_0 - \lambda \partial_z) \partial_z^{-1}) \nu(z, t, \lambda, \tau) f_n(\zeta + \tau z) \}

\[ + (\alpha(n+1) + (\lambda t_0 - \lambda \partial_z)) \nu(z, t, \lambda, \tau) f_{n+1}(\zeta + \tau z) \}. \]

Thus, by putting $P(l, n, \lambda t_0 - \lambda \partial_z) = \alpha(n+1) + (\lambda t_0 - \lambda \partial_z)$, we have (3.11) and (3.12) for $j=1$. Assume (3.11) and (3.12) for some $j$. Then we have
\[ \lambda^{1+\alpha}(\alpha\zeta + (\lambda t_0 - \lambda \partial_2) \partial \zeta)^{t+1} v(z, t, \lambda, \tau) f_n(\zeta + \tau z) \]

\[ \equiv \lambda^{1+\alpha}(\alpha\zeta + (\lambda t_0 - \lambda \partial_2) \partial \zeta) \]

\[ \lambda^{1+\alpha} \left( \sum_{n=0}^{\infty} (-\alpha n^2)_t \partial \zeta)^{t+1} P_i(n, \lambda t_0 - \lambda \partial_2) v(z, t, \lambda, \tau) f_{n+s}(\zeta + \tau z) \right) \]

\[ \equiv \lambda^{1+\alpha} \left( \sum_{n=0}^{\infty} (-\alpha n^2)_t \partial \zeta)^{t+1} P_i(n, \lambda t_0 - \lambda \partial_2) v(z, t, \lambda, \tau) f_{n+s}(\zeta + \tau z) \right) \]

\[ + (\alpha(n+s+1) + (\lambda t_0 - \lambda \partial_2)) \]

\[ \left( \sum_{n=0}^{\infty} (-\alpha n^2)_t \partial \zeta)^{t+1} P_i(n, \lambda t_0 - \lambda \partial_2) v(z, t, \lambda, \tau) f_{n+s}(\zeta + \tau z) \right) \]

\[ \equiv \lambda^{1+\alpha} \left( \sum_{n=0}^{\infty} (-\alpha n^2)_t \partial \zeta)^{t+1} P_i(n, \lambda t_0 - \lambda \partial_2) v(z, t, \lambda, \tau) f_{n+s}(\zeta + \tau z) \right) \]

\[ + (\sum_{n=0}^{\infty} (-\alpha n^2)_t \partial \zeta)^{t+1} (\alpha(n+s+1) + (1-\alpha)) P_i(n, \lambda t_0 - \lambda \partial_2) v(z, t, \lambda, \tau) f_{n+s}(\zeta + \tau z) \]

\[ + (\sum_{n=0}^{\infty} (-\alpha n^2)_t \partial \zeta)^{t+1} (\alpha(n+s+1) + (1-\alpha)) P_i(n, \lambda t_0 - \lambda \partial_2) v(z, t, \lambda, \tau) f_{n+s}(\zeta + \tau z) \].

By putting \( P_{l+1}^k(n, \lambda t_0 - \lambda \partial_2) = P_i(n, \lambda t_0 - \lambda \partial_2) + (\alpha(n+s+1) + (1-\alpha)) P_{l+1}(n, \lambda t_0 - \lambda \partial_2) \), we have (3.11) and (3.12) for \( j+1 \).

Thus, making full use of the above Lemmas, we have

**Proposition 3.5.** The following holds:

\[ \mathcal{L}_{\alpha} V(z, t, \lambda, \zeta, \tau) = \]

\[ \sum_{n=0}^{\infty} \tau_{n+\tau+1}(k-l) \lambda^{(1-\alpha)l} \sum_{n=s}^{m} (-\alpha n^2)_t \partial \zeta)^{t+1} P_i(n+s+r, \lambda t_0 - \lambda \partial_2) \]

\[ \lambda^{k-(1-\alpha)l} \sum_{n=s}^{m} (-\alpha n^2)_t \partial \zeta)^{t+1} a_{k-l, s}(z, \partial) \partial \delta v(z, t, \lambda, \tau) \]

Now let us construct a formal solution \( V(z, t, \lambda, \zeta, \tau) \) of

(3.14)

\[ \mathcal{L}_{\alpha} V(z, t, \lambda, \zeta, \tau) = F(z, t, \lambda, \tau) f_{n_0}(\zeta + \tau z) \]

which has the form (3.9). Define

(3.15)

\[ Q_{l+1}(n, \lambda t_0 - \lambda \partial_2) = \lambda^{k-(1-\alpha)l} \sum_{n=s}^{m} (-\alpha n^2)_t \partial \zeta)^{t+1} P_i(n+s+r, \lambda t_0 - \lambda \partial_2) \]

where \( 0 \leq k \leq m, \ s \leq l \leq k \) and \( 0 \leq r \leq k - l \). By operating \( \mathcal{L}_{\alpha} \) to \( V(z, t, \lambda, \zeta, \tau) \) and setting the coefficients of the same \( f_n(\zeta + \tau z) \) equal to each other, we have from Proposition 3.5

(3.16)

\[ \sum_{n+s+r+d=n} \sum_{n=s}^{m} \sum_{n=s}^{m} (-\alpha n^2)_t \partial \zeta)^{t+1} a_{k-l, s}(z, \partial) \partial \delta v(z, t, \lambda, \tau) \]

\[ \lambda^{k-(1-\alpha)l} \sum_{n=s}^{m} (-\alpha n^2)_t \partial \zeta)^{t+1} a_{k-l, s}(z, \partial) \partial \delta v(z, t, \lambda, \tau) = \delta_{n, n_0} F(z, t, \lambda). \]
In order to show Theorems in § 1 we'll put \( a = a_i = (\sigma_i - 1)/\sigma_i \) or \( a = a_{p-1} = (\sigma_{p-1} - 1)/\sigma_{p-1} \). So we give a lemma for later purposes.

**Lemma 3.6.** Assume \( d_{k, i} = l + j(k, l) \geq +\infty \). Then there are nonnegative \( \beta_{k, i} \in \mathbb{Q} \) \((1 \leq i \leq p - 1)\) such that

\[
(d_{k, i - 1} - d_{k, i})(1 - \alpha_i) + \beta_{k, i} = k_{i-1} - k,
\]

\((k, d_{k, i}) \in \Sigma(i)\) if and only if \( \beta_{k, i} = 0 \), and

\[
\left\{ \begin{array}{l}
(d_{k, i} - d_{k, i})(\alpha_i - \alpha_i) + \beta_{k, i} - \beta_{k, i} + \beta_{k, i} = 0, \\
d_{k, i - 1}(\alpha_i - \alpha_i) + \beta_{k, i - 1} = d_{k, i}(\alpha_i - \alpha_i) + \beta_{k, i},
\end{array} \right.
\]

where \( \beta_{k, i} = \beta_{k, i - 1} \) \( (\text{see } (1.3)) \).

Lemma 3.6 follows from the lower convexity of \( \Sigma \) and the definition of \( \Sigma(i) \) and \( d_{k, i} \) \( (\text{see } [12]) \). Now put \( a = a_i = (\sigma_i - 1)/\sigma_i \) \((1 \leq i \leq p - 1)\). From Lemma 3.6, \( k - d_{k, i}(1 - \alpha_i) = k_{i-1} - d_{k, i - 1}(1 - \alpha_i) - \beta_{k, i} \). Hence we have from (3.16),

\[
\lambda^{k_{i-1} - (1 - \alpha_i) + \sum_{r = 0}^{\infty} \left( \begin{array}{c} k_i - 1 - 1 \end{array} \right) \lambda^{-\alpha_i - l - \beta_{k, i}}}
\]

\[
\sum_{0 \leq d \leq l} (-\alpha_i z_i)^{-d} Q^{\lambda_{i-1}}_{l+r, a(n + s + r, \lambda t_0 - \lambda \partial \lambda) \tau^{d_{k, i - 1} - d} a_{k, i - 1} (z, \partial \lambda \partial \lambda)}
\]

\[= \delta_N, n \mathcal{F}(z, t, \lambda) \].

Put

\[
G_i(z, \partial \lambda, \lambda, \tau) = \lambda^{k_{i-1} - (1 - \alpha_i) + \sum_{r = 0}^{\infty} \left( \begin{array}{c} k_i - 1 - 1 \end{array} \right) \lambda^{-\alpha_i - l - \beta_{k, i}}}
\]

\[
\sum_{0 \leq d \leq l} (-\alpha_i z_i)^{-d} Q^{\lambda_{i-1}}_{l+r, a(n + s + r, \lambda t_0 - \lambda \partial \lambda) \tau^{d_{k, i - 1} - d} a_{k, i - 1} (z, \partial \lambda \partial \lambda)}
\]

\[= \delta_{N, n} \mathcal{F}(z, t, \lambda) \].

\( G_i(z, \partial \lambda, \lambda, \tau) \) is a polynomial of \( \tau \). So we denote it by \( G_i(z, \lambda, \tau) \), which will often appear and has the form

\[
G_i(z, \lambda, \tau) = \lambda^{k_{i-1} - (1 - \alpha_i) + \sum_{r = 0}^{\infty} \left( \begin{array}{c} k_i - 1 - 1 \end{array} \right) \lambda^{-\alpha_i - l - \beta_{k, i}}}
\]

\[
\sum_{0 \leq d \leq l} (-\alpha_i z_i)^{-d} Q^{\lambda_{i-1}}_{l+r, a(n + s + r, \lambda t_0 - \lambda \partial \lambda) \tau^{d_{k, i - 1} - d} a_{k, i - 1} (z, \partial \lambda \partial \lambda)}
\]

\[= \delta_{N, n} \mathcal{F}(z, t, \lambda) \].

Thus the equation (3.19) becomes

\[
G_i(z, \lambda, \tau) v_N(z, t, \lambda, \tau)
\]

\[+ \sum G_i(z, \partial \lambda, \lambda, \tau) v_N(z, t, \lambda, \tau) = \delta_N, n \mathcal{F}(z, t, \lambda, \tau) \],

where \( \sum \) is a finite sum. Consequently we can determine \( v_N(z, t, \lambda, \tau) \) \((N \geq n_0)\) successively by (3.22). In order to determine them we need the division by
So the properties and the estimates of \( v_n(z, t, \lambda, \tau) \) depend on the zeros of \( G(z, \lambda, \tau) \). In particular, if \( F(z, t, \lambda, \tau) \) is rational in \( \tau \), \( v_n(z, t, \lambda, \tau) \) \((N \geq n_e)\) are also rational functions of \( \tau \). \( G^e(z, \lambda, \tau) \) is simple. The zeros of \( G(z, \lambda, \tau) \) are studied in §6.

§4. Construction of Kernels \( G(w, z, t) \) and \( G_R(w, z, t) \)

In §4 we construct \( G(w, z, t) \) and \( G_R(w, z, t) \) in Theorem 1.11 by using the results in §3. So we assume (1.17)-(a), (b), (c) in this section. Now put \( \alpha = \alpha_{p-1} \) and \( \tau = 0 \) in (3.14). Consider

\[
\mathcal{L}_n V(z, t, \lambda, \zeta) = F(z, t, \lambda) f_n(\zeta),
\]

where

\[
F(z, t, \lambda) = \frac{-1}{(2\pi i)^n} \prod_{i=1}^{n} \frac{1}{(t_i - z_i)}
\]

Since \( \alpha = \alpha_{p-1}, \tau = 0 \) and \( d_{k_{p-1}} = 0 \), we have from (3.21)

\[
G(z, \lambda) = G^e(z, \lambda, 0) = \lambda^{k_p-1} \sum_{k \in \mathbb{Z}^n, k_{p-1} = 0} \lambda^{-\beta_{k_{p-1}}^e} a_{k, 0}(z)
\]

If \( k \neq k_{p-1}, \beta_{k_{p-1}}^e > 0 \) in (4.3). By the assumption (1.17)-(c) we have \( |G(z, \lambda)| \geq C|\lambda|^{k_p-1}, C > 0 \), for large \( \lambda \) and in a neighbourhood of \( z = 0 \). So we can construct a formal solution \( V(z, t, \lambda, \zeta) \) of (4.1) by the method in §3,

\[
V(z, t, \lambda, \zeta) = \sum_{n=-1}^{\infty} v_n(z, t, \lambda)f_n(\zeta).
\]

\( v_n(z, t, \lambda) \) \((n \geq -1)\) are successively determined by the formula (3.22) as holomorphic functions in a neighbourhood of \( z = 0 \). We have

**Proposition 4.1.** For small \( r_1, r_2, r_3, 0 < r_1 < r_2 < r_3 \) and large \( A_0 \), there exist constants \( A \) and \( B \) such that

\[
|\lambda^{k_p-1} v_n(z, t, \lambda)| \leq AB^{n+1} (\sum_{j=1}^{n} |\lambda t_j|^r/r!) (n+1)!
\]

holds in \((z, t, \lambda); |z| \leq r_1, |t_0| \leq r_2, r_3 \leq |t_i| \leq r_3 \((1 \leq i \leq n), |\lambda| \geq A_0 \).

The proof of Proposition 4.1 is given in §7. As for the convergence of \( V(z, t, \lambda, \zeta) \), we have

**Proposition 4.2.** \( V(z, t, \lambda, \zeta) = \sum_{n=-1}^{\infty} v_n(z, t, \lambda)f_n(\zeta) \) converges in \((z, t, \lambda, \zeta); |z| \leq r_1, |t_0| \leq r_2, r_3 \leq |t_i| \leq r_3 \((1 \leq i \leq n), |\lambda| \geq A_0, 0 < |\zeta| \leq r_4 \) for some \( r_4 > 0 \), the singularity at \( \zeta = 0 \) of \( V(z, t, \lambda, \zeta) - v_{-1}(z, t, \lambda)f_{-1}(\zeta) \) is logarithmic and

\[
|V(z, t, \lambda, \zeta) - v_{-1}(z, t, \lambda)f_{-1}(\zeta)| \leq A|\lambda|^{e^*} \exp(C*|\lambda t_0|)(|\log |\zeta|| + B)\]
for some constants $A$, $B$, $C^*$ and $q^*$.

Proof. By Proposition 4.1, $|\lambda^{k-1}(V(z, t, \lambda, \zeta) - V_0(z, t, \lambda))| \leq A|\log \zeta| + 1)\sum_{n=0}^{\infty} (B|\zeta|^{n}(\sum_{l=0}^{\infty} |\lambda|^l/r!))$. If $|\zeta| \leq B^{-1}$, $\sum_{n=0}^{\infty} (B|\zeta|)^{n}(\sum_{l=0}^{\infty} |\lambda|^l/r!) \leq A + \sum_{n=0}^{\infty} (|\lambda|^l/r!)(\sum_{n=0}^{\infty} B|\zeta|^{n-1}) \leq A + \sum_{n=0}^{\infty} (|\lambda|^l/r!)(\sum_{n=0}^{\infty} B|\zeta|^{n-1}) \leq A + |\lambda|/\exp(|\lambda|^l/r!)$. So we have (4.6).

The constants $C^*$ and $q^*$ appearing in this section are those in Proposition 4.2. Define paths in $\mathcal{E}$-space: $Z(\psi, \phi') = \{\zeta = d^{s}e^{\psi}((1-s)\psi + \alpha \phi') : 0 \leq s \leq 1\}$ and $Z(\psi, \phi') = \{\phi + 2\pi/\alpha\}$, where $d^s > 0$. Put

\[(4.7) \quad \hat{V}(\psi, \phi, \zeta) = \int_{\mathcal{E}} \exp(-\lambda^a\zeta) V(z, t, \lambda, \zeta) d\zeta,
\]

where $0 < d^s \leq r_s$, $r_s$ being that in Proposition 4.2, and

\[(4.8) \quad \hat{V}(\psi, \phi', z, t, \lambda) = \hat{V}(\psi, \phi, z, t, \lambda) - \hat{V}(\phi', z, t, \lambda),
\]

where $|\alpha(\phi - \phi')| < \pi$. In the definition of $\hat{V}(\psi, \phi, z, t, \lambda)$, the holomorphic part of $V(z, t, \lambda, \zeta)$ as a function of $\zeta$ can be neglected. We have

**Lemma 4.3.** The following estimates hold:

\[(4.9) \quad |\hat{V}(\psi, \phi, z, t, \lambda)| \leq A|\lambda|^s \exp(d^s|\lambda| + C^*|\lambda|^r)|\lambda|^t.
\]

If $|\lambda + \psi| < \pi/2\alpha$,

\[(4.10) \quad |\hat{V}(\psi, \phi, z, t, \lambda)| \leq A|\lambda|^s \exp(C^*|\lambda|^r|\lambda|^t).
\]

If $-(\pi/2\alpha) + (|\phi - \psi|/2) + \epsilon < \arg(\psi + \phi)/2 < (\pi/2\alpha) - (\phi + \psi')/2 < (\pi/2\alpha)$, where $0 < \alpha < (\pi/2\alpha) - (\phi - \psi')/2$,

\[(4.11) \quad |\hat{V}(\psi, \phi', z, t, \lambda)| \leq A|\lambda|^s \exp(C^*|\lambda|^r|\lambda|^t - d^s \sin(\alpha s)|\lambda|^a).
\]

Proof. $\hat{V}(\psi, \phi, z, t, \lambda)$ is well defined and we have (4.9) and (4.10) from (6.6) and the deformation of the integration path $Z(\psi)$. We have

\[(4.12) \quad \hat{V}(\psi, \phi', z, t, \lambda) = \int_{Z(\psi')} \exp(-\lambda^a\zeta) V(z, t, \lambda, \zeta) d\zeta
\]

and $\Re \lambda^a\zeta \geq d^s \sin(\alpha s)|\lambda|^a$ on $Z(\psi + 2\pi/\alpha, \phi' + 2\pi/\alpha) \cup Z(\psi, \phi')$. Thus we have (4.11).

By Lemma 4.3 we can define

\[(4.13) \quad G(\phi; w, z, t) = \int_{\lambda_0} e^{\zeta z} \hat{V}(\phi; z, t, \lambda) d\lambda.
\]
\[ G(\phi, \phi'; w, z, t) = G(\phi; w, z, t) - G(\phi'; w, z, t) \]

\[ = \int_{A_0} \exp(-\lambda w) \hat{V}(\phi, \phi'; z, t, \lambda) d\lambda. \]

Put, by using the constants in Proposition 4.1,

\[
\begin{align*}
\mathcal{X} &= \{(z, t)' \mid z \leq r, \ t \leq r, \ r \leq |t| \leq r \ (1 \leq i \leq n)\}, \\
\mathcal{Q} &= \{z \mid |z| \leq r\}, \quad \mathcal{U} = \{z \mid |z| \leq r\}, \\
\mathcal{X}_{A_0} &= \mathcal{X} \times \mathbb{T}, \quad \mathcal{M}_\mathcal{X} = \{\lambda \mid |\lambda| \geq A_0\},
\end{align*}
\]

and recall (see § 1)

\[ (4.15) \]

\[
W_\delta = \{(w, z, t) \mid |w| > \begin{pmatrix} \sin \delta \end{pmatrix}|t_0|, \ (z, t) \in \mathcal{X} \} \quad \text{for a small } \delta > 0,
\]

the function space $K(W_\delta)$ (see Definition 1.10), and

\[ (4.16) \]

\[
\alpha = \alpha_{p-1} = (\sigma_{p-1} - 1)/\sigma_{p-1}, \quad \gamma = \sigma_{p-1} - 1 = \alpha/(1 - \alpha).
\]

We choose $d^* > 0$ small in the following in this paper, if necessary. We have

**Proposition 4.4.** (1) $G(\phi; w, z, t) \in K(W_\delta)$, $\delta^* = \sin^{-1} C^* d^*$.

(2) Suppose $|\arg w - \phi| < \pi/2 + \pi/2 - \varepsilon$ for small $\varepsilon > 0$. Then if $C^* d^* |t_0| < (\sin \varepsilon) |w|$,\n
\[ (4.18) \]

\[
|\partial^*_z \partial^*_t G(\phi; w, z, t)| \leq \frac{A B^* C^* q! r!}{(\sin \varepsilon) |w| - C^* d^* |t_0|} q^{q^*+1}.
\]

(3) Suppose $|\arg w - \phi| < \pi$. Then there is $0 < c^* \leq 1$ such that if $C^* d^* |t_0| < c^* |w|$,\n
\[ (4.19) \]

\[
|\partial^*_z \partial^*_t G(\phi; w, z, t)| \leq \frac{A B^* C^* q! r!}{c^* |w| - C^* d^* |t_0|} q^{q^*+1}.
\]

Constants $A$, $B$ and $C$ in (4.18)-(4.19) are some constants and $q^*$ is that in (4.6) (or (4.10)), and $\partial^*_z$ stands for the $r$-th derivative with respect to $z$.

**Proof.** By varying $\varphi$ in (4.13), we have the holomorphic prolongation of $G(\phi; w, z, t)$ with respect to $w$ and $G(\phi; w, z, t) \in K(W_\delta)$ by (4.9). Suppose $|\arg w - \phi| < \pi/2 + \pi/2 - \varepsilon$. Then we can choose $\lambda = |\lambda| e^{i\varphi}$ ($|\varphi + \phi| < \pi/2\alpha$) such that $\Re \lambda w \geq (\sin \varepsilon) |\lambda w|$. Hence, if $C^* d^* |t_0| < (\sin \varepsilon) |w|$,\n
\[
|\partial^*_z G(\phi; w, z, t)| \leq A \int_{A_0} \exp(-(\sin \varepsilon) |\lambda w| + C^* d^* |\lambda t_0|) |\lambda|^{q^*+1} |d\lambda|
\]

\[
\leq A B^* q! ((\sin \varepsilon) |w| - C^* d^* |t_0|)^{-q^*-1}.
\]
We have also the similar estimates for \( \partial_\phi \partial^{*}_\phi G(\phi; w, z, t) \). In particular suppose 
\( |\arg w - \phi| < \pi \). Then we can choose \( \lambda = |\lambda| e^{i\alpha} \) \((|\varphi + \phi| > \pi/2\alpha)\) so that \( \text{Re} \lambda w \geq c^*|\lambda w| \), where \( 0 < c^* \leq 1 \) is determined by \( \alpha \). Hence, if \( C^*d^*|t_o| < c^*|w| \),

\[
|\partial_\phi \partial^{*}_\phi G(\phi; w, z, t)| \leq A \int_{t_o} \exp(-c^*|\lambda w| + C^*d^*|\lambda t_o|)|\lambda|^{q-a^*}d\lambda \leq A B^q ! (c^*|w| - C^*d^*|t_o|)^{-q-a^*}.
\]

Thus we have (4.19).

We study \( G(\phi; w, z, t) \) in §4 and §5. We calculate \( L(z, \partial_\phi) G(\phi; t_0 - z_0, z, t) \) in this section. In the following \( \equiv \) means modulo holomorphic functions on \( X \) (see (4.15)). We have

**Proposition 4.5.**

(4.20)

\[
L(z, \partial_\phi) G(\phi; t_0 - z_0, z, t) = \frac{-1}{(2\pi i)^{n+1}} \prod_{t_i=z_i} (t_i-z_i)^{-1} + G_R(\phi; t_0 - z_0, z, t),
\]

where

(4.21)

\[
G_R(\phi; w, z, t) = \int_{t_o} \exp(-\lambda w - \lambda^a d^a e^{i\alpha \psi}) V_R(\phi; z, t, \lambda) d\lambda
\]

and \( V_R(\phi; z, t, \lambda) \equiv \mathcal{O}(X_{\lambda_o}) \) with

(4.22)

\[ |V_R(\phi; z, t, \lambda)| \leq A(1 + |\lambda|)^N \exp(C^*d^*|\lambda t_o|) \quad \text{for some } N. \]

Before the proof of Proposition 4.5 we note the following identity:

\[
L_{k, i}(z, \partial) G(\phi; t_0 - z_0, z, t) = z_o^i a_{k,i}(z, \partial') \partial^{k+I} G(\phi; t_0 - z_0, z, t)
\]

\[
= \int_{t_o} \exp(-\lambda(t_o - z_0) z_o^i \partial^{i+1} \exp(-\lambda^a \zeta) V(z, t, \lambda, \zeta) d\lambda
\]

\[
= \int_{t_o} (\partial^{i+1} \exp(-\lambda z_o) \exp(-\lambda t_o) d\lambda
\]

\[
\times \int_{\mathbb{C}^n} a_{k,i}(z, \partial') (\partial^{i+1} \exp(-\lambda^a \zeta) V(z, t, \lambda, \zeta) d\zeta.
\]

Now we give several lemmas to show Proposition 4.5, in which the same notation \( \tilde{V}(z, t, \lambda) \) means several functions on \( X_{\lambda_o} \).

**Lemma 4.6.**
\[(4.23) \quad \int_{\mathcal{P}(\phi)} (\partial_t + \lambda)^{k-1} \exp(-\lambda^a \xi) V(z, t, \lambda, \xi) d\xi \]
\[\quad = \lambda^{k-1} \int \exp(-\lambda^a \xi)(\lambda^{-1-a} \partial_t \partial_{\xi}^{-1} + 1)^{k-1} V(z, t, \lambda, \xi) d\xi \]
\[\quad + \exp(-\lambda^a d^a e^{4a}) \tilde{V}(z, t, \lambda), \]
where \(|\tilde{V}(z, t, \lambda)| \leq A(1 + |\lambda|)^N \exp(C d^a |\lambda t_b|)\) for some \(N\).

**Proof.** Since \(\partial_t \exp(-\lambda^a \xi) = -\lambda^a \exp(-\lambda^a \xi)\) and \((\partial_t + \lambda)^{k-1} = (\lambda^{-1-a} \partial_t \partial_{\xi}^{-1} + 1)^{k-1}\), we have (4.23) by integration by parts with respect to \(\xi\).

**Lemma 4.7.**
\[(4.24) \quad \int_{\mathcal{P}(\phi)} a_k(z, \partial^2) (\partial_t + \lambda)^{k-1} \exp(-\lambda^a \xi) V(z, t, \lambda, \xi) d\xi \]
\[\quad = \lambda^{k-1-a} \int \exp(-\lambda^a \xi) a_k(z, \partial^2) (\lambda^{-1-a} \partial_t \partial_{\xi}^{-1} + \lambda)^{k-1} V(z, t, \lambda, \xi) d\xi \]
\[\quad + \exp(-\lambda^a d^a e^{4a}) \tilde{V}(z, t, \lambda), \]
where \(|\tilde{V}(z, t, \lambda)| \leq A(1 + |\lambda|)^N \exp(C d^a |\lambda t_b|)\) for some \(N\).

**Proof.** We have (4.24) with another \(\tilde{V}(z, t, \lambda)\) and another \(N\) in the same way as in Lemma 4.6, by using integration by parts in \(\xi\).

Put
\[(4.25) \quad V^*_{k,t}(z, t, \lambda, \xi) = \lambda^{k-1-a} a_k(z, \partial^2) (\lambda^{-1-a} \partial_t \partial_{\xi}^{-1} + \lambda)^{k-1} V(z, t, \lambda, \xi). \]

**Lemma 4.8.** The following identity holds:
\[(4.26) \quad \int_{A_0} \int_{\mathcal{P}(\phi)} (\partial_t^j \exp(\lambda z_0)) \exp(-\lambda t_b) d\lambda \int \exp(-\lambda^a \xi) V^*_{k,t}(z, t, \lambda, \xi) d\xi \]
\[\quad \equiv \int_{A_0} \int \exp(-\lambda(t_b - z_0)) d\lambda \]
\[\times \int \exp(-\lambda^a \xi)(\lambda^{-1-a}(\partial_t - \lambda \partial_{\xi}^{-1} + \lambda^a \xi) V^*_{k,t}(z, t, \lambda, \xi) d\xi \]
\[\quad + \int \exp(-\lambda(t_b - z_0) - \lambda^a d^a e^{4a}) \tilde{V}(z, t, \lambda) d\lambda, \]
where \(|\tilde{V}(z, t, \lambda)| \leq A(1 + |\lambda|)^N \exp(C d^a |\lambda t_b|)\) for some \(N\).

**Proof.** By integration by parts in \(\lambda\), we have
By integrations by parts in $\zeta$ we have

$$
\int_{\mathbb{C}^n} \exp(-\lambda \zeta(t_0 - z_0)) d\lambda \int_{\mathbb{C}^n} \exp(-\lambda \zeta) V_{\psi}(z, t, \lambda, \zeta) d\zeta
$$

$$
= \int_{\mathbb{C}^n} \exp(-\lambda \zeta(\alpha \lambda^{n-1} t + t_0 - \partial_\zeta) V_{\psi}(z, t, \lambda, \zeta) d\zeta
$$

$$
+ \exp(-\lambda \zeta d^* e^{i\alpha \psi}) V(z, t, \lambda).
$$

Hence we have (4.26).

Summing up Lemmas 4.6-4.8, we have from (3.1)

**Lemma 4.9.** The following holds:

$$
(4.27) \quad L_{z_0} \psi \left( z, t : -z_0, z, t \right) \equiv \int_{\mathbb{C}^n} \exp(-\lambda(t_0 - z_0)) d\lambda \int_{\mathbb{C}^n} \exp(-\lambda \zeta) V_{\psi}(z, t, \lambda, \zeta) d\zeta
$$

$$
= \int_{\mathbb{C}^n} \exp(-\lambda(t_0 - z_0)) \left[ \exp(-\lambda \zeta) \right] \psi(z, t, \lambda, \zeta) d\zeta + \int_{\mathbb{C}^n} \exp(-\lambda \zeta) \psi(z, t, \lambda, \zeta) d\zeta
$$

$$
= \exp(-\lambda \zeta(t_0 - z_0) - \lambda^a d^* e^{i\alpha \psi}) V_{\psi}(z, t, \lambda, \zeta)
$$

where $|V_{\psi}(z, t, \lambda)| \leq A(1 + |\lambda|)^N \exp(C^* d^N |\lambda_0|)$ for some $N$.

Now we can give the proof of Proposition 4.5.

**Proof of Proposition 4.5.** We have, by Lemma 4.9,

$$
(4.28) \quad L(z, \partial_\zeta) \psi \left( z_0 : -z_0, z, t \right) \equiv \int_{\mathbb{C}^n} \exp(-\lambda(t_0 - z_0)) d\lambda \int_{\mathbb{C}^n} \exp(-\lambda \zeta) V_{\psi}(z, t, \lambda, \zeta) d\zeta
$$

$$
= \int_{\mathbb{C}^n} \exp(-\lambda \zeta) \left[ \exp(-\lambda \zeta) \right] \psi(z, t, \lambda, \zeta) d\zeta + \int_{\mathbb{C}^n} \exp(-\lambda \zeta) \psi(z, t, \lambda, \zeta) d\zeta
$$

$$
= \exp(-\lambda(t_0 - z_0) - \lambda^a d^* e^{i\alpha \psi}) V_{\psi}(z, t, \lambda, \zeta)
$$

where $|V_{\psi}(z, t, \lambda)| \leq A(1 + |\lambda|)^N \exp(C^* d^N |\lambda_0|)$ for some $N$. Define

$$
(4.29) \quad G_{\psi}(\psi; w, z, t) \equiv \int_{\mathbb{C}^n} \exp(-\lambda w - \lambda^a d^* e^{i\alpha \psi}) V_{\psi}(z, t, \lambda, \zeta) d\lambda.
$$

Then, from (4.1), we have
We have shown in Proposition 4.4 that \( G(\psi ; w, z, t) \in \mathcal{K}(W_8) \). It is obvious that \( G(\psi ; w, z, t) \) and \( G(\phi, \psi ; w, z, t) \) are also in \( \mathcal{K}(W_8) \). In the next section we show that \( G(\phi; w, z, t), G(\phi; w, z, t) \) and \( G(\phi, \psi; w, z, t) \) have the properties (1)-(5) stated in Theorem 1.11.

§ 5. Integral Operators

In this section we firstly study integral operators with kernels \( K(w, z, t) \in \mathcal{K}(W_8) \) and secondly give the proof of Theorem 1.11. Let us recall \( \langle w, z, t \rangle \in C^1 \times C^{n+1} \times C^{N+1}, t=(t_1, t_2, \cdots, t_N), \) \( X=\{(z, t)\in C^N \times C^{N-1}; \; \vert z \vert \leq r_1, \; \vert t \vert \leq r_3, \; r_5 \leq \vert t_i \vert \leq r_2 \; (1 \leq i \leq N)\}, \)

\begin{equation}
W_8=\{(w, z, t)\in C^1 \times C^{n+1} \times C^{N+1}; \; \vert w \vert > (\sin \delta) \vert t_0 \vert, \; (z, t) \in X\},
\end{equation}

where \( 0<r_1<r_3<r_5 \) and \( \delta>0 \) is small and put

\begin{equation}
\begin{cases}
U=\{z\in C^{n+1}; \; \vert z \vert \leq r_1\}, \\
Q=\{t\in C^{N+1}; \; \vert t \vert \leq r_3\}, \\
X_{\lambda}=X \times \mathbb{A}^{r_5}, \; \mathbb{A}^{r_5}=\{\lambda \in C^N; \; \vert \lambda \vert \geq \lambda_0\}.
\end{cases}
\end{equation}

We also write again a path \( T(a, b) \) in \( t \)-space, \( a<b \) and \( b-a \leq 2\pi \) (see §1), which is defined as follows: \( T(a, b)=T_0(a, b) \times T' \subset C^1 \times C^{N} \). \( T_0(a, b)=T_0(a, b)+T_1(a, b)+T_2(a, b) \) is a path in \( t_0 \)-space, where \( T_0(a, b)=\{t_0=:(1-s)\varphi r_3+s\eta \varphi e^{i\varphi}; \; 0 \leq \varphi \leq 1\} \), \( T_1(a, b)=\{t_1=r_2(1-s)\eta e^{i\eta}; \; 0 \leq \eta \leq 1\} \), \( T_2(a, b)=\{t_3=r_3(1-s)\eta e^{i\eta}; \; 0 \leq \eta \leq 2\pi\} \). \( T' \) is the product of paths \( |t_i|=r_3 \) \( (t_1=r_3 e^{i\varphi}; \; 0 \leq \varphi \leq 2\pi) \) \( (i=1, 2, \cdots, N) \) in \( C^N \). \( \eta>0 \) in \( T_0(a, b) \) is chosen suitably and small in order to obtain good estimates.

Let \( K(w, z, t) \in \mathcal{K}(W_8) \) and \( f(t) \in \mathcal{O}(Q(a, b)), \; b-a>2\delta \). Define

\begin{equation}
(Kf)(z)=\int_T K(t_0-z_0, z, t)f(t)dt,
\end{equation}

where \( T=T(a', b') \) with \( a<a'<b' <b \) and \( 2\delta < b'-a' \leq 2\pi \). We have

**Proposition 5.1.** Let \( K(w, z, t) \in \mathcal{K}(W_8) \) and \( f(z) \in \mathcal{O}(Q(a, b)), \; b-a>2\delta \). Then \( (Kf)(z) \in \mathcal{O}(U(a+\delta, b-\delta)). \)
Proof. We note that \( K(w, z, t) \) is holomorphic if \(|w| > (\sin \delta)|t_o| \) as a function of \( w \). So, if \( z_o \) satisfies \(|z_o - t_o| > (\sin \delta)|t_o| \) for \( t_o \in T_o(a', b') \), \((Kf)(z)\) is holomorphic. So we obtain \((Kf)(z) \in C(U(a' + \delta, b' - \delta))\). The integration path \( T \) depends on \( a' \) and \( b' \). Let \((K'f)(z)\) be an operator integrated on \( T(a', b') \) and \((K''f)(z)\) be one integrated on \( T(a'', b'') \). We can easily show that if \((a' + \delta, b' - \delta) \cap (a'' + \delta, b'' - \delta) = \emptyset\), then \((K'f)(z) - (K''f)(z)\) is holomorphic in a neighbourhood of \( z = 0 \). Thus \((Kf)(z)\) is holomorphically extensible to \( U(a + \delta, b - \delta) \).

**Proposition 5.2.** Suppose that \( \hat{K}(z, t, \lambda) \in \mathcal{O}(X_{\lambda_0}) \) satisfies

\[
(5.4) \quad |\hat{K}(z, t, \lambda)| \leq A \exp (|\sin \delta| |\lambda_t| + B |\lambda|^{\alpha}) \quad \text{on } X_{\lambda_0}
\]

for \( A, B, 0 < \alpha < 1 \) and \( 0 \leq \delta < \pi/2 \). Put

\[
(5.5) \quad K(w, z, t) = \int_{\lambda_0}^{w} \exp(-\lambda w)\hat{K}(z, t, \lambda) d\lambda.
\]

Then \( K(w, z, t) \in \mathcal{K}(W_0) \) and the following holds.

1. Let \( f(z) \in \mathcal{O}_{\lambda_1, h}(\Omega(\phi + (\pi/2) - \varepsilon_o, -\phi + (3\pi/2) + \varepsilon_o)), \varepsilon_o > \delta, \gamma = \alpha/(1 - \alpha) \). Then for any \( \varepsilon' > 0 \) there is an \( h'(\varepsilon') \) such that \( (Kf)(z) \in \mathcal{O}_{\lambda_1, h}(\Omega(\phi + (\pi/2) + \varepsilon', -\phi + (3\pi/2) - \varepsilon')) \).

2. Suppose that

\[
(5.6) \quad |\hat{K}(z, t, \lambda)| \leq A \exp (|\sin \delta| |\lambda_t| - C |\lambda|^{\alpha}) \quad \text{on } \arg \lambda = \phi.
\]

Let \( f(z) \in \mathcal{O}_{\lambda_1, h}(\Omega(\phi + (\pi/2) - \varepsilon_o, -\phi + (3\pi/2) + \varepsilon_o)), \varepsilon_o > \delta, \gamma = \alpha/(1 - \alpha) \). Then there is an \( h_1 \) such that if \( 0 < h < h_1 \), \((Kf)(z) \in \text{Asy}_{\lambda_1}(U(\phi + (\pi/2), -\phi + (3\pi/2)) \).

3. Suppose that

\[
(5.7) \quad |\hat{K}(z, t, \lambda)| \leq A (1 + |\lambda|^\alpha) \exp (|\sin \delta| |\lambda_t|) \quad \text{on } \arg \lambda = \phi.
\]

Let \( \kappa > 0 \) be arbitrary. If \( f(z) \in \mathcal{O}_{\lambda_1, h}(\Omega(\phi + (\pi/2) - \varepsilon_o, -\phi + (3\pi/2) + \varepsilon_o)), \varepsilon_o > \delta, \delta' > \varepsilon' \), then for any \( \varepsilon' > 0 \) there is a constant \( c = c(\varepsilon') > 0 \) such that \((Kf)(z) \in \mathcal{O}_{\lambda_1, c}(\Omega(\phi + (\pi/2) + \varepsilon', -\phi + (3\pi/2) - \varepsilon')) \). If \( f(z) \in \text{Asy}_{\lambda_1}(\Omega(-\phi + (\pi/2) - \varepsilon_o, -\phi + (3\pi/2) + \varepsilon_o)), \varepsilon_o > \delta, \delta' > \varepsilon' \), then \((Kf)(z) \in \text{Asy}_{\lambda_1}(\Omega(-\phi + (\pi/2), -\phi + (3\pi/2)) \).

Proof. It is obvious that \( K(w, z, t) \in \mathcal{K}(W_0) \). Put \( \Psi(\lambda, t_o) = -\text{Re} \lambda t_o + (\sin \delta) |\lambda_t| + h |t_o|^{1-\alpha} + B |\lambda|^{\alpha}, \delta_o = (\delta + \varepsilon_o)/2 \) and \( T = T(-\phi + (\pi/2) - \delta', -\phi + (3\pi/2) + \delta') \). Let \( \lambda = \phi \). Put \( \eta = c |\lambda|^{-1-\alpha} \) in the definition of \( T \). Then we have \( \Psi(\lambda, t_o) \leq (B + hc\gamma) |\lambda|^{\alpha} \) on \( T(\phi + (\pi/2) - \delta', -\phi + (3\pi/2) + \delta') \), \( c_1 = \sin \delta' - \sin \delta \). So \( \Psi(\lambda, t_o) \leq (B + hc\gamma) |\lambda|^{\alpha} \) on \( T(\phi + (\pi/2) - \delta', -\phi + (3\pi/2) + \delta') \).

We have also, \( \Psi(\lambda, t_o) \leq (B + hc\gamma) |\lambda|^{\alpha} \) on \( T(\phi + (\pi/2) - \delta', -\phi + (3\pi/2) + \delta') \). On \( T(\phi + (\pi/2) - \delta', -\phi + (3\pi/2) + \delta') \), \( \Psi(\lambda, t_o) \leq (c + c \sin \delta + hc\gamma + B) |\lambda|^{\alpha} \). Hence we have
(5.8) \[ \Psi(\lambda, t_0) \leq (c + c \sin \delta + hc^{-t} + B) |\lambda|^a \quad \text{on} \quad T_0\left(-\phi + \frac{\pi}{2} - \delta', -\phi + \frac{3\pi}{2} + \delta'\right). \]

So we have, if \( \arg \lambda = \phi \),

(5.9) \[ \left| \int_T \exp(-\lambda t_0)K(z, t, \lambda) f(t) dt \right| \leq A \exp ((c + c \sin \delta + hc^{-t} + B) |\lambda|^a) \]

for any \( c > 0 \). Thus we have, if \( |\arg z_0 + \phi - \pi| < (\pi/2) - \varepsilon' \),

(5.10) \[ (Kf)(z) = \int_{\gamma} \exp(\lambda z_0) \int_T \exp(-\lambda t_0)K(z, t, \lambda) f(t) dt \]

and from (5.9)

\[ |(Kf)(z)| \leq A \left| \int_{\gamma} \exp(-(\sin \varepsilon') |z_0| r + (c + c \sin \delta + hc^{-t} + B)r^a) dr \right| \leq A |z_0|^{-N-1} \exp (h' |z_0|^{-\gamma}). \]

We have (1). Let us show (2). Assume (5.6). Put \( \Psi(\lambda, t_0) = -\Re \lambda t_0 + (\sin \delta) |\lambda t_0| + h |t_0|^{-\gamma}, T = T\left(-\phi + (\pi/2) - \delta', -\phi + (3\pi/2) + \delta'\right), \delta' = (\delta + \varepsilon_0)/2 \) and let \( \arg \lambda = \phi \). Put \( \eta = c |\lambda|^{-1-\gamma} \) in the definition of \( T \). Then we have

(5.11) \[ \Psi(\lambda, t_0) \leq (c + c \sin \delta + hc^{-t}) |\lambda|^a \quad \text{on} \quad T\left(-\phi + \frac{\pi}{2} - \delta', -\phi + \frac{3\pi}{2} + \delta'\right). \]

So we have, if \( \arg \lambda = \phi \),

(5.12) \[ \left| \int_T \exp(-\lambda t_0)K(z, t, \lambda) f(t) dt \right| \leq A \exp ((c + c \sin \delta + hc^{-t} - C) |\lambda|^a) \]

for any \( c > 0 \) and if \( |\arg z_0 + \phi - \pi| < \pi/2 \),

\[ |(Kf)(z)| \leq A \left| \int_{\gamma} \exp((c + c \sin \delta + hc^{-t} - C)r^a) dr \right|. \]

Choose \( c > 0 \) small so that \( c + c \sin \delta \leq 2c \leq C/4 \), fix it and choose \( h_1 \) with \( h_1c^{-t} \leq C/4 \). Hence if \( 0 < h < h_1 \), for \( |\arg z_0 + \phi - \pi| < \pi/2 \)

(5.13) \[ |(Kf)(z)| \leq A \left| \int_{\gamma} \exp(-Cr^a/2) dr \right|. \]

We also have

(5.14) \[ |\partial_R(Kf)(z)| \leq A \sum_{i=0}^N \left| \int_{\gamma} \exp(-C |\lambda|^{-a}/2(1 + |\lambda|)^a) d\lambda \right| \leq AB^* \Gamma\left(\frac{r}{a} + 1\right). \]

This means that if \( 0 < h < h_1, (Kf)(z) \in \text{Asy}_{1/2}(U(-\phi + (\pi/2), -\phi + (3\pi/2)), \eta = c |\lambda|^{-1-\gamma} \right). T' = (-\phi + (\pi/2) - \delta', -\phi + (3\pi/2) + \delta'), T'' = (\delta + \varepsilon_0)/2 \), and \( \arg \lambda = \phi \). We have in the same way as in (1), for any \( c > 0 \)

(5.15) \[ \left| \int_T \exp(-\lambda t_0)K(z, t, \lambda) f(t) dt \right| \leq A(1 + |\lambda|)^N \exp ((c + c \sin \delta + hc^{-t}) |\lambda|^a), \]
\[ a = \frac{\kappa}{1+\kappa}. \]

Hence we have for \(-\phi + (\pi/2) < \arg z < -\phi + (3\pi/2),\]

\begin{equation}
(Kf)(z) = \int_{A_0} \exp(\lambda z_0) d\lambda \int_T \exp(-\lambda t_0) K(z, t, \lambda)f(t)dt
\end{equation}

and

\begin{equation}
| (Kf)(z) | \leq A \int_{A_0} \exp(\Re \lambda z_0 + (c + c \sin \delta + hc^{-\varepsilon})|\lambda|^{\hat{\alpha}}(1 + |\lambda|)^N) d\lambda.
\end{equation}

Choose \( c = h^{1/(r+1)} \), then \( c + c \sin \delta + hc^{-\varepsilon} = \hat{\alpha} h^{1-\hat{\alpha}} \) for a \( \hat{\alpha} > 0 \) independent of \( h \). Thus we have for \(-\phi + (\pi/2) + \varepsilon < \arg z < -\phi + (3\pi/2) - \varepsilon' \)

\begin{equation}
| (Kf)(z) | \leq A \int_0^\infty \exp(-\sin \varepsilon' \arg z | r + \hat{\alpha} h^{1-\hat{\alpha}} |(1 + r)^N) dr
\end{equation}

\[ \leq A |z_0|^{-N-1} \exp (c'h |z_0|^{-r}) \leq A \exp (c' h |z_0|^{-r}), \quad c = c(\varepsilon'). \]

This means the first statement of (3). Let us show the second statement of (3). Let \( f(z) \in \mathcal{A}_{\varepsilon_0} \mathcal{Q}(-\phi + (\pi/2) - \varepsilon_0, -\phi + (3\pi/2) + \varepsilon_0) \). Then we have

\begin{equation}
\int_T \exp(-\lambda t_0) K(z, t, \lambda)f(t)dt
\end{equation}

\[ = \int_T \exp(-\lambda t_0) K(z, t, \lambda) \left( \sum_{k=0}^{\infty} \lambda^k t_0^k \partial_{t_0}^k f(0, t')/k! + t_0^{q+1} f(t)/(q+1) \right) dt. \]

Put

\[ g_q(z, \lambda) = \int_T \exp(-\lambda t_0) K(z, t, \lambda) \left( \sum_{k=0}^{\infty} \lambda^k t_0^k \partial_{t_0}^k f(0, t')/k! \right) \]

and

\[ h_q(z, \lambda) = \int_T \exp(-\lambda t_0) K(z, t, \lambda) t_0^{q+1} f(t)/(q+1)! dt. \]

By deforming the path \( T \) and putting \( c_z = (\sin \delta' - \sin \delta) r_0 > 0 \), we have

\[ |g_q(z, \lambda)| \leq A |\lambda|^N \exp(-c_z|\lambda|) \left( \sum_{k=0}^{\infty} A B^k \Gamma \left( \frac{k}{\kappa} + 1 \right) \right) \]

\[ \leq A |\lambda|^N \exp(-c_z|\lambda|) B^q \Gamma \left( \frac{q+1}{\kappa} + 1 \right) \leq A |\lambda|^{N-q} B^q \Gamma \left( \frac{q+1}{\kappa} + 1 \right) \]

for \( \arg \lambda = \phi \),

and

\[ |h_q(z, \lambda)| \leq \int_T \exp(-\lambda t_0) K(z, t, \lambda) t_0^{q+1} f(t)/(q+1)! dt \]

\[ \leq A |\lambda|^N \int_T \exp(-c_z|\lambda| t_0^q) B t_0^q \Gamma \left( \frac{q+1}{\kappa} + 1 \right) dt \]

\[ \leq A |\lambda|^{N-q} \int_T \exp(-c_z|\lambda| t_0^q) B t_0^q \Gamma \left( \frac{q+1}{\kappa} + 1 \right) dt \]
\[ \leq A|\lambda|^{N-\epsilon-1}C(\delta', \delta')^{\frac{q+1}{\kappa}+1}(q+1)! \quad \text{for } \arg \lambda = \phi. \]

Therefore we have for \( \arg \lambda = \phi \)
\begin{equation}
(5.20) \left| \int t \exp(-\lambda t_{0})K(z, t, \lambda)f(t)dt \right| \leq A|\lambda|^{N-\epsilon-1}B(\delta', \delta')^{\frac{q+1}{\kappa}+1}(q+1)!. \tag{5.20}
\end{equation}

Since the estimate (5.20) is valid for large \( \lambda \) and any \( q \in \mathbb{N} \),
\begin{equation}
(5.21) \left| \int t \exp(-\lambda t_{0})K(z, t, \lambda)f(t)dt \right| \leq A(\epsilon, \delta) \exp(-c|\lambda|^{\delta}), \quad \delta = \frac{\epsilon}{\kappa+1}. \tag{5.21}
\end{equation}

Hence we have if \( |\arg z_{0}+\phi-\pi| < \pi/2 \),
\begin{equation}
(5.22) \quad (Kf)(z) = \int_{0}^{\epsilon} \exp(\lambda z_{0})d\lambda \int \exp(-\lambda t_{0})K(z, t, \lambda)f(t)dt
\end{equation}
and from (5.21)
\begin{equation}
(5.23) \quad |\partial_{\alpha}(Kf)(z)| \leq AB^{r} \sum_{i=0}^{r} \left| \int_{0}^{\epsilon} \frac{\exp(-c|\lambda|^{\delta}) (1+|\lambda|)^{r}d\lambda}{} \right| \leq AB^{r} \Gamma\left(\frac{r}{\alpha}+1\right). \tag{5.23}
\end{equation}
This means that \((Kf)(z) \in \text{Asy}_{i=0}(U(-\phi-(\pi/2), -\phi+(3\pi/2))).\)

Now we apply Propositions 5.1 and 5.2 to the integral operators defined by (5.3) with kernels \( K(w, z, t) = G(\phi; w, z, t), G_{R}(\phi; w, z, t) \) or \( G(\phi', \phi''; w, z, t) \) (see (4.13), (4.14) and (4.21)). They are denoted by \((G_{\phi}f)(z), (G_{R}f)(z)\) or \((G_{\phi'} \phi'' f)(z)\) respectively. In the following considerations
\begin{equation}
(5.24) \quad a = \alpha_{p-1} = (\sigma_{p-1}-1)/\sigma_{p-1}, \quad \text{and} \quad \gamma = \sigma_{p-1}-1 = \alpha_{p-1}/(1-\alpha_{p-1}),
\end{equation}

From Lemma 4.3 and (4.22) we have the estimates:
\begin{equation}
(5.25) \quad |\hat{\psi}(\phi; z, t, \lambda)| \leq A|\lambda|^{|\phi'|-1} \exp((\sin|\delta|)|\lambda|^{\alpha} + d^{|\phi'|}|\lambda|^{\alpha}),
\end{equation}
\begin{equation}
(5.26) \quad |\hat{\psi}(\phi; z, t, \lambda)| \leq A|\lambda|^{|\phi'|-1} \exp((\sin|\delta|)|\lambda|^{\alpha}) \quad \text{for } |\arg \lambda + \phi| < \pi/2\alpha,
\end{equation}
\begin{equation}
(5.27) \quad |\hat{\psi}(\phi', \phi''; z, t, \lambda)| \leq A|\lambda|^{|\phi'-1} \exp((\sin|\delta|)|\lambda|^{\alpha} - d^{|\phi'|} \sin(\alpha\epsilon)|\lambda|^{\alpha})
\end{equation}
for \( \frac{-\pi}{2\alpha} + \frac{|\phi'-\phi'|}{2} + \epsilon < \arg \lambda + \frac{\phi' + \phi''}{2} < \frac{-\pi}{2\alpha} + \frac{|\phi'-\phi'|}{2} - \epsilon \) with
\[0 < \alpha \epsilon < \frac{\pi}{2} - \frac{\alpha|\phi'-\phi'|}{2}\]
and
\begin{equation}
(5.28) \quad |\exp(-\lambda d^{*} e^{i\alpha\phi})V_{R}(\phi; z, t, \lambda)| \leq A(1+|\lambda|)^{N} \exp((\sin|\delta|)|\lambda|^{\alpha} - d^{*} \sin(\alpha\epsilon)|\lambda|^{\alpha}) \quad \text{for } |\arg \lambda + \phi| < \frac{\pi}{2\alpha} - \epsilon.
\end{equation}

**Proposition 5.3.** Let \( f(z) \in O_{(\gamma, \lambda)}(Q(a, b)), \) where \( \phi-\pi/2a+\pi/2 < a < b < \phi+\pi/2 \).
\[ \frac{\pi}{2a} + \frac{3\pi}{2}, b-a>\pi+2\delta^*. \] Then for any \( \varepsilon>\delta^* \) there is a constant \( c=c(\varepsilon)>0 \) such that \( (G^{\phi}f)(x) \in \mathcal{O}_{17.1}(U(a+\varepsilon, b-\varepsilon)) \).

**Proof.** Put \( K(z, t, \lambda) = \tilde{\psi}(\phi; z, t, \lambda) \) in Proposition 5.2. Choose \( \varepsilon_0 \) so that \( b-a>\pi+2\varepsilon_0>\pi+2\delta^* \) and \( \varepsilon>\varepsilon_0 \). Then it follows from the assumption on \( a \) and \( b \) that \( \tilde{\psi} \) with \( a-(\pi/2)+\varepsilon_0<-\tilde{\psi}<b-(3\pi/2) \) satisfies \( |\tilde{\psi}+\tilde{\phi}|<\varepsilon_0 \) and (5.26) holds. Hence it follows from Proposition 5.2-(3) that for any \( \varepsilon'>0 \) there is a \( c=c(\varepsilon')>0 \) such that \( (G^{\phi}f)(z)^0 \in \mathcal{O}_{17.1}(U(-\tilde{\phi}+\pi/2+\varepsilon', -\tilde{\phi}+3\pi/2-\varepsilon')) \). The union of intervals \((-\tilde{\phi}+(\pi/2)+\varepsilon', -\tilde{\phi}+(3\pi/2)-\varepsilon')\), \( a-(\pi/2)+\varepsilon_0<-\tilde{\psi}<b-(3\pi/2)-\varepsilon_0 \), is \((a+\varepsilon_0+\varepsilon', b-\varepsilon_0-\varepsilon')\). By putting \( \varepsilon' = \varepsilon - \varepsilon_0 \), we have the assertion.

**Proposition 5.4.** Suppose \( \phi'<\phi^* \), \( 0<\alpha\delta^*< \frac{\pi}{2}\alpha \). Let \( f(z) \in \mathcal{O}_{17.1, h}(\Omega(a, b)) \), where \( \phi'-\frac{\pi}{2}\alpha < a < b < \phi'+\frac{\pi}{2}\alpha + 3\pi/2 \) and \( b-a>\pi+2\delta^* \). Then there is an \( h_0 \) such that if \( 0<h<h_0 \), \( (G^{\phi'}\phi^*)f(z) \in \text{Asy}_{17.1}(\Omega(a+\delta^*, b-\delta^*)) \).

**Proof.** Put \( K(z, t, \lambda) = V(\phi', \phi^*; z, t, \lambda) \) in Proposition 5.2. Choose \( \varepsilon_0 \) so that \( b-a>\pi+2\varepsilon_0>\pi+2\delta^* \) and \( \alpha\varepsilon_0<\frac{\pi}{2}\alpha \). Then it follows from the assumption on \( a \) and \( b \) that \( \tilde{\psi} \) with \( a-(\pi/2)+\varepsilon_0<-\tilde{\psi}<b-(3\pi/2) \) satisfies \( |\tilde{\psi}+\tilde{\phi}|<\varepsilon_0 \) and (5.27) holds for \( \arg \lambda = \tilde{\lambda} \) and \( \varepsilon = \varepsilon_0 \), where \( \sin(\alpha\varepsilon_0) \geq \sin(\alpha\delta^*) \). Intervals \((-\tilde{\phi}+(\pi/2), -\tilde{\phi}+(3\pi/2))\), \( a-(\pi/2)+\varepsilon_0<-\tilde{\psi}<b-(3\pi/2)-\varepsilon_0 \), cover \((a+\varepsilon_0, b-\varepsilon_0)\). We have the assertion by Proposition 5.2-(2), tending \( \varepsilon_0 \) to \( \delta^* \).

**Proposition 5.5.** Let \( f(z) \in \mathcal{O}_{17.1, h}(\Omega(a, b)) \), where \( \phi-\frac{\pi}{2}\alpha < a < b < \phi+\frac{\pi}{2}\alpha + 3\pi/2 \), \( b-a>\pi+2\delta^* \). Then there is an \( h_0(\delta^*) > 0 \) such that, if \( 0<h<h_1 \), \( (G^{\phi}f)(z) \in \text{Asy}_{17.1}(U(a+\delta^*, b-\delta^*)) \).

**Proof.** Put \( K(z, t, \lambda) = \exp(-\lambda^* d^*(\phi^*)) V_R(z, t, \lambda) \) in Proposition 5.2. Choose \( \varepsilon_0 \) so that \( b-a>\pi+2\varepsilon_0=\pi+2\delta^* \). Then it follows from the assumption on \( a \) and \( b \) that \( \tilde{\psi} \) with \( a-(\pi/2)+\varepsilon_0<-\tilde{\psi}<b-(3\pi/2) \) satisfies \( |\tilde{\psi}+\tilde{\phi}|<\varepsilon_0 \) and (5.28) holds for \( \varepsilon = \varepsilon_0 \). Intervals \((-\tilde{\phi}+(\pi/2), -\tilde{\phi}+(3\pi/2))\), \( a-(\pi/2)+\varepsilon_0<-\tilde{\psi}<b-(3\pi/2)-\varepsilon_0 \), cover \((a+\varepsilon_0, b-\varepsilon_0)\). By tending \( \varepsilon_0 \) to \( \delta^* \), since \( \sin(\alpha\varepsilon_0) \geq \sin(\alpha\delta^*) \), we have the assertion from Proposition 5.2-(2).

Now let \( \delta_0 > 0 \) be a given small number. We choose \( d^* = d^*(\delta_0) > 0 \) so that \( e^* \sin \delta_0 = C^* d^* \), by using the constants \( 0 < e^* \leq 1 \) and \( C^* > 0 \) in Proposition 4.4, and fix \( d^* \). It is obvious that \( \delta_0 \geq \delta^* = \frac{1}{\sin^{-1} C^* d^*} \). In the rest of this section we consider \( G(\phi; w, z, t) \), \( G_R(\phi; w, z, t) \) and \( G(\phi', \phi^*; w, z, t) \) for this fixed \( d^* = d^*(\delta_0) \). By Proposition 4.4, if \( |\arg w-\phi|<\pi \), and \( (\sin \delta_0)|t_1|<|w| \),

\begin{equation}
\left| \frac{\partial^2 \tilde{\psi}; G(\phi; w, z, t)}{\partial \tilde{\phi}^2} \right| \leq \frac{AB^3 C q' r!}{(e^* (|w| - \sin \delta_0 |t_1|))^{q+r+1}}, \quad q' = q + q^* \nonumber
\end{equation}

holds.
**Proposition 5.6.** Let \( f(z) \in \text{Asy}_{\kappa}(\Omega(a, b)) \), where \( \kappa > 0 \) is arbitrary, \( \phi \leq b - 2\pi < a < b \). Then \( (G^k f)(z) \in \text{Asy}_{\kappa}(U(a + \delta_0, b - \delta_0)) \).

**Proof.** We may assume \( \phi = -\pi \). Let \( a < b < a' < b' < b < b' \) with \( b' - a > 2\delta_0 \) and \( z \in U(a' + \delta_0, b' - \delta_0) \). We have

\[
(\partial_{k_0})^n(G^{-\pi}f)(z) = \int_{T} (-\partial_{w} + \partial_{z_0})^n G(-\pi; t_0 - z_0, z, t) f(t) dt
\]

\[
= \int_{T} G^{(q)}(-\pi; t_0 - z_0, z, t) (\sum_{k=0}^{n} t_k (\partial_{z_0})^k f(0, t')/k! + t_0^{q-1} \tilde{f}(t)/(q' + 1) !) dt,
\]

where \( T = T(a', b') \), \( G^{(q)}(-\pi; w, z, t) = (-\partial_{w} + \partial_{z_0})^q G(-\pi; w, z, t) \) and \( q' = q + q^* \). Put

\[
g_q(z) = \int_{T} G^{(q)}(-\pi; t_0 - z_0, z, t) (\sum_{k=0}^{n} t_k (\partial_{z_0})^k f(0, t')/k!) dt
\]

and

\[
h_q(z) = \int_{T} G^{(q)}(-\pi; t_0 - z_0, z, t) t_0^{q-1} \tilde{f}(t)/(q' + 1) ! dt.
\]

By deforming the path \( T \), we have \( g_q(z) \in O(U) \) and \( |g_q(z)| \leq q ! \sum_{k=0}^{n} A B^k C^k \Gamma \times ((k + 1)/\kappa + 1) \leq A B^q D q ! \Gamma((q' + 1)/\kappa + 1) \). Since \( -\pi < a < a' < b' < b < b' \), \( b' - a > 2\delta_0 \), there is a \( \delta > 0 \) such that \( \sin \delta < |z_0 - t_0| \) for \( t \in T = T(a', b') \) and \( z \in U(a' + \delta_0, b' - \delta_0) \), and since \( t \in T = T(a', b') \subset \Omega(-\pi, \pi) \) and \( z \in U(a' + \delta_0, b' - \delta_0) \subset U(-\pi, \pi) \), \( |\arg(t_0 - z_0) - \pi| < \pi \). Therefore by (5.29)

\[
|h_q(z)| \leq A q ! \int_{T} \frac{B^q |t_0|^q \Gamma \left( \frac{q' + 1}{\kappa} + 1 \right)}{|(t_0 - z_0) - \sin \delta_0| t_0 | \tilde{f}(t) |^q !} dt_0.
\]

\[
\leq A q ! \int_{T} \frac{B^q |t_0|^q \Gamma \left( \frac{q' + 1}{\kappa} + 1 \right)}{|(\sin \delta_0 - \sin \delta_0) | t_0 | \tilde{f}(t) |^q !} dt_0 \leq A q ! B^q \Gamma \left( \frac{q' + 1}{\kappa} + 1 \right).
\]

Thus we have

\[
|\partial_{z_0}^n(\tilde{G}^{-\pi}f)(z)| \leq |g_q(z)| + |h_q(z)| \leq AB^q \Gamma \left( \frac{q' + 1}{\kappa} + 1 \right)
\]

for \( z \in U(a' + \delta_0, b' - \delta_0) \). This means \( (G^{-\pi}f)(z) \) has the \( \kappa \)-asymptotic expansion in \( U(a' + \delta_0, b' - \delta_0) \). Since \( a' \) and \( b' \) are arbitrary, \( (G^{-\pi}f)(z) \) has the \( \kappa \)-asymptotic expansion in \( U(a + \delta_0, b - \delta_0) \).

Now we show (1)-(5) in Theorem 1.11.

**Proof of Theorem 1.11.** It follows from Proposition 4.5 that
where $T_c$ is a path $T_x \times T'$, $T_x = T_0(a, b) = \{t_0 = r \theta^{(z-1)(-\pi+b+\delta)}; 0 \leq s \leq 1\}$. The last term integrated on $T_c$ is holomorphic at $z=0$. So we have (1) in Theorem 1.11. We proceed to the proof of (2)-(4). Let $f(z) \in \mathcal{O}(Q(a, b))$. We have (2) in Theorem 1.11 by Proposition 5.3, (3) by Proposition 5.4 and (4) by Proposition 5.6. Finally we show (5). If $b-a > \pi+2\delta$, it follows from Proposition 5.5. Otherwise, by Proposition 2.12, we have for given $h'$ with $h_1 > h' > h$, $h_1$ being that in Proposition 5.5, $f(z) = f_1(z) + f_2(z)$, where $f_1(z) \in \mathcal{O}_{171, a}(Q(a-2\pi, b))$, $f_2(z) \in \mathcal{O}_{171, a}(Q(a, b+2\pi))$. We have, from the assumptions on $a$ and $b$, $\phi - \pi/2 < a - \pi < b < \phi + \pi/2 < 2\pi$. Hence by Proposition 5.5, $(G^2 f_i)(z) \in \text{Asy}_{171}(U(a+\delta, b-\delta))$ and $(G^2 f_3)(z) \in \text{Asy}_{171}(U(a+\delta, b+\pi-\delta)).$ Since $(G^2 f) = (G^2 f_1)(z) + (G^2 f_2)(z), \ (\mod \mathcal{O}(U))$, $(G^2 f)(z) \in \text{Asy}_{171}(U(a+\delta, b-\delta))$.

§ 6. Integral Representation

In §6 we obtain an integral representation of a solution $u(z) \in \mathcal{O}(Q(\theta_0))$ of

$$L(z, \partial_z)u(z) = f(z),$$

where $f(z) \in \mathcal{O}(Q(\theta_0))$. When $f(z) \in \mathcal{O}(Q)$, an integral representation was obtained in [6], [7] and [12]. In this section we assume (1.11)-(a), (b), (c), namely,

$$(a) \quad \sigma > 1 , \quad (b) \quad d_{k-p-1} = 0 , \quad (c) \quad d_{k-s} = s_{k-s} \quad \text{for} \ 0 \leq s \leq p - 2.$$

So we have

$$L(z, \partial_z) = \sum_{k=0}^{p} \sum_{i=1}^{k} A_k, i(z, \partial') \partial'^{-i},$$

where $d_{k-s} = s_{k-s} \ (0 \leq s \leq p-1)$, that is, $l_{k-s} = s_{k-s}, \ f(k, \ l_k) = 0$ and $A_{k, s}(z, \partial') = a_{k, s}(z, \partial')$ and by (6.2)-(b) $d_{k-s} = s_{k-s} = 0$. Put $\xi' = (1, 0, \cdots, 0)$. First we assume

$$A_{m, s}(0, \xi') = a_{m, s}(0, \xi') = 0,$$

$$\prod_{l=1}^{p+1} A_{k, t}(0, \xi') = \prod_{l=1}^{p+1} A_{k, s}(0, \xi') = 0 \quad \text{(see (1.14))}. $$

We construct an integral representation and investigate it under the conditions (6.4). An integral representation can be constructed under the condition on the principal part in (6.4), and other conditions on lower order terms are used for the proof of Theorem 6.28 which requires detailed analysis of the integral representation.
Before construction, we give a remark on the coordinate $z$. From (6.2) and (6.4) the principal part of $L(z, \partial_z)$ is written in the form

\[(6.5) \quad L_m(z, \partial_z) = \sum_{i=0}^{m} A_{m,i}(z, \partial_z) \partial_z^{m-i}, \quad A_{m,0}(0, \xi') \neq 0.\]

Consider the coordinate transformation

\[(6.6) \quad w_0 = z_0, \quad w_i = c z_0 + z_i, \quad w_i = z_i \quad (i \geq 2).\]

Then we have

\[(6.7) \quad L_m(z, \partial_z) = \sum_{i=0}^{m} A_{m,i}(z(w), \partial_w) \partial_{w_0} + c \partial_{w_1})^{m-i}.\]

The coefficient of $(\partial_{w_0})^m$ is $(\sum_{i=0}^{m} c^{m-i} A_{m,i}(0, \xi'))$ at the origin. Since $A_{m,0}(0, \xi') \neq 0$, the coefficient of $(\partial_{w_1})^m$ does not vanish for large $c$. This means $w_1 = 0$ is non characteristic. Hence in addition to (6.3)-(6.4) we assume that the coordinate is chosen so that

\[(6.8) \quad A_{m, m}(0, \xi') \neq 0,\]

that is, $z_1 = 0$ is non characteristic.

The integral representation obtained here has the form

\[(6.9) \quad u(z) = \frac{1}{2\pi i} \sum_{h=0}^{m-1} \int_{\gamma_h \times T^*} K^h(t_0 - z_0, z, t_0, t^*) u_h(t_0, t^*) dt_0 dt^*\]

\[+ \frac{1}{2\pi i} \int_{\gamma} K^m(t_0 - z_0, z, t) f(t) dt,\]

where $u_h(t_0, t^*) = (\partial/\partial t^*)^h u(t_0, 0, t^*)$ and the integration paths $T^* = T^0(a, b), 0 < b - a \leq 2\pi, T = T^0 \times T'$ and $T^*$ are defined in §1. The functions $\{K^h(w, z, t_0, t^*) ; 0 \leq h \leq m - 1\}$ do not depend on $t_1$, but for simplicity we denote them by $K^h(w, z, t)$ and the same conventions will be used for other functions. We seek for the kernel functions $K^h(w, z, t)$ ($0 \leq h \leq m$) in the following form,

\[(6.10) \quad K^h(w, z, t) = \int_{\gamma_h} \exp(-\lambda u)d\lambda \int_{\gamma} \exp(-\lambda u \xi) W^h(z, t, \lambda, \xi)d\xi,\]

where

\[(6.11) \quad \alpha = \alpha_i = (\sigma_i - 1)/\sigma_i.\]

We note that $\alpha$ defined by (6.11) is different from $\alpha$ in §4. The integration path $C$ in $\xi$-space in (6.10) will be defined later.

We construct $K^h(w, z, t)$ ($0 \leq h \leq m$) by the method described in §3. As in §3, we define the integro-differential operator $\mathcal{L}_\alpha(z, \lambda, \xi, \partial_z, \partial_\lambda, \lambda \partial_z - \xi \partial_\lambda)$ for $\alpha = (\sigma_i - 1)/\sigma_i$. We will determine $W^h(z, t, \lambda, \xi)$ ($0 \leq h \leq m$) by
Firstly we reduce the initial value problem (6.12) to that with zero initial data. In order to do so we give a lemma.

**Lemma 6.1.** Let 
\[ \varphi(\tau) = \sum_{k=0}^{m-1} a_k \tau^k \quad (a_m \neq 0). \]
For given \( \{b_k ; 0 \leq k \leq m-1\} \) there exists uniquely a polynomial \( \varphi(\tau) \) with degree \( < m \) such that
\[ \int_{|\tau| = \epsilon} \frac{\tau^k \varphi(\tau)}{\varphi(\tau)} \, d\tau = b_k \quad \text{for } 0 \leq k \leq m-1, \]
where \( \epsilon \) is chosen so that all the roots of \( \varphi(\tau) = 0 \) are contained in \( \{\tau ; |\tau| < \epsilon\} \).

**Proof.** We may assume \( a_m = 1 \). Put
\[ \varphi(\tau) = \sum_{j=0}^{m-1} a_j \tau^{p-j} \quad (j=0, 1, \cdots, m-1). \]
Then we have
\[ \int_{|\tau| = \epsilon} \frac{\tau^k \varphi(\tau)}{\varphi(\tau)} \, d\tau = \delta_{k,b}. \]
Hence \( \varphi(\tau) = \sum_{j=0}^{m-1} b_j \varphi_j(\tau) \) is a desired polynomial. It is easy to show the uniqueness.

We can define by Lemma 6.1 a polynomial \( \varphi^h(z^\tau, t, \tau) \) with degree \( < m \) such that
\[ \int_{|\tau| = \epsilon} \frac{\tau^k \varphi^h(z^\tau, t, \tau)}{(\tau - t)^m} \, d\tau = \delta_{k,h} \quad \text{for } 0 \leq k \leq m-1, \]
where \( \tau \) is a positive constant. Later we will choose \( \tau \) so as to satisfy an inequality and fix it. Using \( \varphi^h(z^\tau, t, \tau) \), define
\[ \varphi^h(z^\tau, t, \tau) = \frac{\varphi^h(z^\tau, t, \tau)}{(\tau - t)^m} f_{-1}\varphi(\zeta + \tau z_i) \]
and
\[ \varphi^h(z^\tau, t, \tau) = \int_{|\tau| = \epsilon} \frac{\varphi^h(z^\tau, t, \tau)}{(\tau - t)^m} \, d\tau \quad c > \tau_i. \]
Then, if \( |\zeta| > c|z_i| \), we have for \( 0 \leq k \leq m-1 \)
\[ \int_{|\tau| = \epsilon} \frac{\tau^k \varphi^h(z^\tau, t, \tau)}{(\tau - t)^m} f_{-1}\varphi(\zeta + \tau z_i) \, d\tau \mid_{z_i = 0} \]
\[ = -\frac{\delta_{h,k}}{(2\pi i)^n} \Pi_{-2} \frac{1}{(t_i - z_i)} f_{-1}\varphi(\zeta) = -\frac{\delta_{h,k}}{(2\pi i)^n + i\epsilon} \Pi_{-2} \frac{1}{(t_i - z_i)}. \]
Hence \( V^h(z, t, \lambda, \zeta) = W^h(z, t, \lambda, \zeta) - \hat{V}^h(z, t, \zeta) \) satisfies the zero initial conditions
\[
(\partial_t)^k V^h(z, t, \lambda, \zeta) \big|_{z=0} = 0 \quad \text{for } 0 \leq k \leq m-1.
\]

Put
\[
C^h(z, t, \lambda, \zeta) = \mathcal{L}_a(z, \lambda, \zeta, \partial_z, \lambda t_0 - \lambda \partial_z) V^h(z, t, \lambda, \zeta).
\]

It is easy to show that if \(|\zeta| > |cz_1|\),
\[
C^h(z, t, \lambda, \zeta) = \sum_{k=0}^{m-1} c_{h,k}(z, t, \lambda, \tau) f_k(\zeta + \tau z_1) d\tau,
\]
where
\[
c_{h,k}(z, t, \lambda, \tau) = \frac{-\delta_{h,m}}{(2\pi i)^{n+2}} \left( \prod_{i=1}^{n-1} \frac{1}{(t_i - z_1)} \right) \frac{1}{\tau} + \frac{\delta_{h,k} c_{k-1}(z, t, \lambda, \tau)}{(\tau - \tau_i)^m},
\]
where \( c_{h,k}(z, t, \lambda, \tau) \) \((-1 \leq k \leq m + h - 1\)) are polynomials of \( \tau \) with degree \( < m \), and \( c_{h,k}(z, t, \lambda, \tau) = 0 \). Thus the initial value problem (6.12) is equivalent to
\[
\mathcal{L}_a(z, \lambda, \zeta, \partial_z, \lambda t_0 - \lambda \partial_z) W^h(z, t, \lambda, \zeta) = C(t, z, \lambda, \zeta),
\]
\[
(\partial_z)^k W^h(z, t, \lambda, \zeta) \big|_{z=0} = 0 \quad \text{for } 0 \leq k \leq m-1,
\]
where we denote \( V^h(z, t, \lambda, \zeta) \) again by \( W^h(z, t, \lambda, \zeta) \). We try to find \( W^h(z, t, \lambda, \zeta) \) in the form
\[
W^h(z, t, \lambda, \zeta) = \sum_{n=-1}^{m-1} w_n(z, t, \lambda, \tau) f_n(\zeta + \tau z_1),
\]
where \( f_n(\zeta) \) \((n \in \mathbb{Z})\) are defined by (3.4) and the path \(|\tau| = c\) is a circle and encloses \( \tau = 0 \) once, \( c \) being large.

Now let us determine \( w_n(z, t, \lambda, \tau) \) \( (-1 \leq n < +\infty) \) in (6.25). Substituting \( W^h(z, t, \lambda, \tau) \) into (6.24), we have as in § 3 (see (3.21) and (3.22))
\[
G_0(z, \lambda, \tau) w_0^h(z, t, \lambda, \tau) + \sum_{n=1}^{\infty} G_n(z, \lambda, \tau) w_n^h(z, t, \lambda, \tau) = c_{n,0}(z, t, \lambda, \tau),
\]
where
\[
G_0(z, \lambda, \tau) = \frac{1}{\lambda^{m-1}} \mathcal{L}_a(z, \lambda, \zeta, \partial_z, \lambda t_0 - \lambda \partial_z) f(z, \lambda, \tau),
\]
and
\[
G_n(z, \lambda, \tau) = \frac{1}{\lambda^{m-n-1}} \sum_{k=0}^{n} \lambda^{-n-k} \left( \prod_{i=1}^{n-k} (-\alpha_{i} z_1) \right) \mathcal{L}_a(z, \lambda, \zeta, \partial_z, \lambda t_0 - \lambda \partial_z) a_k(z).
\]
(6.28) \[ G_w(z, \partial', \lambda, \tau) = \lambda^{m-(1-a)} d_m \]
\[ \left\{ \sum_{k,l} \sum_{s,t} \frac{a_{k,l,s,t}}{r} \left( \frac{h-l}{r} \right) \lambda^{-(1-a)\tau - \beta k,l, s(t(-\alpha)z)^{j-s}} Q_{l,s}(n+s+r, \lambda t_0 - \lambda \partial) \right\}, \quad j = j(k, l). \]

\( G_w(z, \tau, \lambda) \) is a polynomial of \( \tau \) with degree \( m \) and the coefficient of \( \tau^m \) is \( \lambda^{m-(1-a)} d_m a_{m,m}(z) \) which does not vanish in a neighbourhood of \( z=0 \) by (6.8). So we conclude that \( w^w_n(z, \lambda, \tau) (n \geq -1) \) are successively determined by (6.26) and each \( w^w_n(z, \tau, \lambda) \) is a rational function of \( \tau \). By (6.23), if \( h=m \), its poles are \( \tau=0 \) and \( \{ \tau; G_w(z, \lambda, \tau)=0 \} \) and if \( h \not= m \), its poles are \( \tau \alpha \) and \( \{ \tau; G_w(z, \lambda, \tau)=0 \} \), and the multiplicity of \( \tau \) is \( m \).

Now we investigate the roots of the algebraic equation \( G_w(z, \lambda, \tau)=0 \) under the conditions (6.4) and (6.8) in order to analyze the integral representation. Put
\[ F_0(z, \lambda, \tau) = \sum_{k=0}^m \lambda^{-\beta k,l,1} \tau^l a_{0,1}(z), \]
\[ F_1(z, \lambda, \tau) = \sum_{k,l} \sum_{s} \lambda^{-\beta k,l,1} (-\alpha z)^s \tau^l a_{k,s}(z), \]
\[ 1 \leq i \leq p-1, \]
where \( a_{k,l}(z) = a_{k,l}(z, \xi^i) \) and \( j = j(k, l) \), and
\[ F_0^*(z, \lambda, \tau) = \lambda^{m-(1-a)} d_m G_w(z, \lambda, \tau) - F_1(z, \lambda, \tau). \]

We recall that \( + \infty = \alpha_0 > \alpha_1 > \cdots > \alpha_{p-1} > \alpha_p = 1, \quad \alpha_i = (\alpha_{i-1})/\alpha_i \), \( m = k_0 > k_1 > \cdots > k_{p-1} \geq 0, \quad \beta^{k_1}_{i,1} = k_{i-1} - k -(d_{k_{i-1}} - d_{k,i})(1-\alpha_i) \) and \( \beta^{k_1}_{i,1} = \beta_i^k \) (see §1 and §3). In the sequel \( d_{k-1} = m \) and \( \beta^{k_1}_{i-1} = (m-d_m)(1-\alpha_i) \). We have

**Proposition 6.2.** There are positive constants \( A_0, a_i, b_i \) \((a_i > b_i, 0 \leq i \leq p-1)\), \( C, r \) and \( c \), such that the following holds: Put \( U = \{ z \in \mathbb{C}^{n-1}; |z| \leq r \}, \)
\( Y_i = \{ \tau; b_i |\lambda|^{1-\alpha_i} \leq |\tau| \leq b_{i-1} |\lambda|^{1-\alpha_{i-1}} \} \) \(0 \leq i \leq p-1, b_{-1} = + \infty, \quad Y_i^* = \{ \tau; b_i |\lambda|^{1-\alpha_i} \leq |\tau| \leq b_{i-1} b_i |\lambda|^{1-\alpha_{i-1}}/2 \} \) and \( Y_i^* = \{ \tau; 3b_i |\lambda|^{1-\alpha_i}/2 \leq |\tau| \leq a_i |\lambda|^{1-\alpha_{i-1}/2} \}. \) Let \( z \in U \) and \( |\lambda| \geq A_0 \). Then it holds that
\[ |F_1(z, \lambda, \tau)| \geq C |\lambda|^{-\beta^{k_1}_{i-1}} |\tau|^{d_{k_{i-1}}-1} \quad (0 \leq i \leq p-1) \]
on the boundary of \( Y_i^* \) and
\[ |F_i^*(z, \lambda, \tau)| \leq |\lambda|^{-c} |F_1(z, \lambda, \tau)| \quad (0 \leq i \leq p-1) \]
on the boundary of \( Y_i^* \) and all the nonzero roots of \( F_i(z, \lambda, \tau)=0 \) are contained in \( Y_i^* \).

**Proof.** Put \( \tau = \eta |\lambda|^{1-\alpha_i} \) \((0 \leq i \leq p-1, \alpha_0 = 1) \). Then we have by Lemma 3.6
where \( j = j(k, l) \). Since \( \beta_{k+} + d_{k}(\alpha_{i} - \alpha_{i}) = \beta_{k-} + d_{k-}(\alpha_{i} - \alpha_{i}) \) by Lemma 3.6 and \( d_{k} = s_{k} \), that is, \( j(k, l_{k}) = 0 \), there are \( a_{i} \) and \( b_{i} \), \( a_{i} > b_{i} \), such that \(|F(z, \lambda, \tau)| \geq C |\lambda|^{- \beta_{k-1} |\tau|^{d_{k-1}} - 1} \) on \( \{|\tau| = a_{i} |\lambda|^{- a_{i} + a_{i}} \} \cup \{|\tau| = b_{i} |\lambda|^{- a_{i} + a_{i}} \} \) and all the non zero roots of \( F(z, \lambda, \tau) = 0 \) are contained in \( \{|\tau| ; 2b_{i} |\lambda|^{a_{i} - a_{1}}/2 < |\tau| < a_{i} |\lambda|^{a_{i} - a_{1}}/2 \} \).

Put \( \tau = \eta^{a_{i} + a_{i} - 1} \) \((i \geq 1, \alpha_{0} = 1) \). Then

\[ F(z, \lambda, \eta^{a_{i} + a_{i} - 1}) = \sum_{(k, l) ; (k, d_{k}, l) \in \Sigma(O)} \lambda^{- \beta_{k-1} |\tau|^{d_{k-1}}} \eta^{d_{k-1} |\tau|^{d_{k-1}}} \lambda^{d_{k-1} |\tau|^{d_{k-1}}} \,(z) \]

\[ = \sum_{(k, l) ; (k, d_{k}, l) \in \Sigma(O)} \lambda^{- \beta_{k-1} |\tau|^{d_{k-1}}} \eta^{d_{k-1} |\tau|^{d_{k-1}}} \lambda^{d_{k-1} |\tau|^{d_{k-1}}} \,(z) \],

(j = j(k, l)). Since \( \beta_{k-1} > 0 \) for \((k, l) \in \{k_{i-1}, d_{k_{i-1}}\} \), we have \(|F(z, \lambda, \tau)| \geq C |\lambda|^{- \beta_{k-1} |\tau|^{d_{k-1}} - 1} |\tau|^{d_{k-1}} \) on \( \{|\tau| = b_{i} |\lambda|^{- a_{i} + a_{i}} \} \cup \{|\tau| \geq A_{0} \} \).

Thus we have (6.32). It remains to show (6.33). For each term \( \lambda^{- \beta_{k-1} |\tau|^{d_{k-1}}} \eta^{d_{k-1} |\tau|^{d_{k-1}}} \lambda^{d_{k-1} |\tau|^{d_{k-1}}} \,(z) \) in \( F(z, \lambda, \tau) \), we have \( \lambda^{- \beta_{k-1} |\tau|^{d_{k-1}}} \eta^{d_{k-1} |\tau|^{d_{k-1}}} \lambda^{d_{k-1} |\tau|^{d_{k-1}}} \,(z) \) on the boundary of \( \gamma_{r} \), where \( \beta_{k-1} > 0 \). Hence there is a constant \( c > 0 \) and a large \( A_{0} \) such that (6.33) holds for \( |\lambda| \geq A_{0} \).

Now let \( \tilde{t}_{i, j}(z) \lambda^{a_{i} - a_{1}} \) \((0 \leq i \leq p - 1, 1 \leq j \leq d_{k_{i-1}} - d_{k_{i}}) \) be non zero roots of \( F(z, \lambda, \tau) = 0 \). It follows from \( d_{k_{i-1}} - d_{k_{i}} = m \), and from (6.33) Rouche's Theorem that there are roots of \( G(z, \lambda, \tau) = 0 \), \( \{t_{i, j}(z, \lambda) ; 0 \leq i \leq p - 1, 1 \leq j \leq d_{k_{i-1}} - d_{k_{i}}\} \), such that \(|t_{i, j}(z, \lambda) ; 1 \leq j \leq d_{k_{i-1}} - d_{k_{i}} \} \subset \gamma_{r}^{7} \). More precisely we have

**Proposition 6.3.** For any small \( \eta > 0 \) there are \( A_{0} \) and \( r \) such that \(|t_{i, j}(z, \lambda) \lambda^{a_{i} - a_{1}} - \tilde{t}_{i, j}(0) < \eta/2 \) for \( z \in U = \{|z| \leq r \} \) and \(|\lambda| \geq A_{0} \).

Choose \( \tau_{i} \) in (6.16) so that \( b_{i} < \tau_{i} < a_{i} \) and fix it.

Define for \( 0 \leq i \leq p - 1 \)

\[ K_{i}(\eta) = \{ \tau ; |\tau - \tilde{t}_{i, j}(0)| < \eta \} \]

\[ \tau_{i}(\eta) = K_{i}(\eta) \cup \{ |\tau - \tau_{i}(\eta)| < \eta \} \]

and set \( \tau(i) \) \((0 \leq i \leq p) \), by using the constants \( a_{i} \) and \( b_{i} \) in Proposition 6.2 and small \( \eta > 0 \): for \( 0 \leq i \leq p - 1 \)

\[ \tau(i) = \{ \tau ; |\tau - \tilde{t}_{i, j}(0) \lambda^{a_{i} - a_{1}} | < \eta |\lambda|^{a_{i} - a_{1}} \}

\[ \cap \{ |\tau - \tilde{t}_{i, j}(0) \lambda^{a_{i} - a_{1}} | < \eta |\lambda|^{a_{i} - a_{1}} \} \text{ for } 1 \leq j \leq d_{k_{i-1}} - d_{k_{i}} \}, \]

\[ \eta = \{ \tau ; |\tau| < b_{p-1} \lambda^{a_{p} - a_{1}} \} \]

Proposition 6.3 means that for given small \( \eta \)
SOLUTIONS WITH SINGULARITIES

\[ T_i^r = \{ (r; 3b_t |\lambda|^{a_i-a_1}/2 < |\tau| < a_i |\lambda|^{a_i-a_1}/2) \} \]

for \( z \in U = \{ |z| \leq r \} \) and \( |\lambda| \geq A_0 \). We also define the sets \( \mathcal{E}(i) \)
and \( \mathcal{E}(i) = \{ (z, t, A); (z, t) \in X, |\lambda| \geq A_0, \tau \in \tau(i) \}, 0 \leq i \leq p, \)

\[ \mathcal{E} = \bigcup_{i=1}^{p} \mathcal{E}(i), \]

where \( X = \{ (z, t) \in C^{n+1} \times C^{n-1}; |z| \leq r_1, |t_0| \leq r_2, r_3 \leq |t_4| \leq r_3 (1 \leq i \leq n) \} \) and \( r \) is small and \( A_0 \) is large, if necessary.

We have by the same method as in Proposition 6.2.

**Proposition 6.4.** On \( \{ (z, t, A); |z| \leq r, |\lambda| \geq A_0, \tau \in \tau(i) \} \),

\[ |G_0(z, \lambda, \tau)| \geq C |\lambda|^{nz-a_1} |\tau|^{d_{k_1} - 1}. \]

Let us define sectors \( S_i (0 \leq i \leq p-1) \), which are used in the later part of this sections for analysis of the integral representation. We defined sectors \( S_i (1 \leq i \leq p-1) \) in \([12]\), where \( S_0 \) was not defined, but the following arguments are the same as in \([12]\). To define \( S_i \) we give two lemmas.

**Lemma 6.5.** There is an \( \omega_0 \) such that \( \arg (\tau, \omega_0) = \pi - \pi a_i \) (mod 2\( \pi \)) and \( \arg (\chi_i, \omega_0) = \pi - \pi a_i \) (mod 2\( \pi \)) for all \( 0 \leq i \leq p-1 \) and \( 1 \leq j \leq d_{k_1} - d_k \).

**Proof.** Put \( B = \{ \chi_i, \omega_0 = \pi - \pi a_i \}; r \geq 0 \) and \( L = \bigcup_{i=1}^{p} L_i \). \( B \) is a finite set of nonzero points and \( L \) is a finite set of half lines. So we can find an \( \omega_0 \) such that \( \omega_0 B \cap L = \emptyset \). This implies the assertion.

We have from Lemma 6.5

**Lemma 6.6.** There are \( \omega_1 \) and positive numbers \( r, e_1 \) and \( A_0 \) such that \( \arg (\tau, \omega_1) = \pi - \pi a_i \) (mod 2\( \pi \)) and \( \arg (\chi, \omega_1) = \pi - \pi a_i \) (mod 2\( \pi \)) for all \( |\lambda| \geq A_0, |z| \leq r \) and \( |\omega - \omega_1| < e_1 \).

Thus we have

**Proposition 6.7.** There are \( \eta, e_i > 0 \) and open sectors \( S_i (0 \leq i \leq p-1) \) with the vertex 0 in \( C^1 \) such that \( S_i \supset e_i = \pi \) and \( S_i \cap (-z, K_\eta(\eta/2)) = \emptyset \) (0 \( i \leq p-1 \)) for \( |z| < e_i \).

Now we return to construction of \( w^h(z, t, \lambda, \tau) \) in (6.25). As for estimates of \( w^h(z, t, \lambda, \tau) \) we have

**Proposition 6.8.** There exist positive constants \( A, B \) and \( c \) such that the
following estimates of \(w_h(z, t, \lambda, \tau)\) hold in \(S\). For \(0 \leq h \leq m - 1\)

\[(6.41) \quad |x'(\tau - \tau_\lambda)|^n w_h(z, t, \lambda, \tau)| \leq AB^{n+1} n! \left(\sum_{\tau=\tau_0}^{\tau_1} |\lambda t_0|^r / |\tau|^{n+1}\right) \]

and

\[(6.42) \quad |\tau w_h(z, t, \lambda, \tau)| \leq AB^{n+1} n! \left(\sum_{\tau=\tau_0}^{\tau_1} |\lambda t_0|^r / |\tau|^{n+1}\right). \]

We refer the proof of Proposition 6.8 to §7. The convergence of \(w_h(z, t, \lambda, \zeta, \tau) = \sum_{n=0}^{m-1} w_h(z, t, \lambda, \tau)f_n(\zeta + \tau z_1)\) follows from Proposition 6.8.

**Proposition 6.9.** (1) There is a constant \(c^* > 0\) such that \(w_h(z, t, \lambda, \zeta, \tau)\) converges in \((z, t, \lambda, \zeta, \tau) \in S, \tau \neq 0, \tau_1, \text{ and } 0 < |\zeta + \tau z_1| < c^*|\tau|\).

(2) There exist positive constants \(A, B, C_1\) and \(c'\) such that the following estimates hold:

\[(6.43) \quad |(\tau - \tau_\lambda)^n [w_h(z, t, \lambda, \zeta, \tau) - w_h(z, t, \lambda, \tau)f_n(\zeta + \tau z_1)]| \leq \frac{A}{|\tau|} |\lambda|^c \exp(c^*B|\lambda t_0|)(\text{log}(\zeta + \tau z_1) + C_1) \quad \text{for } 0 \leq h \leq m - 1 \]

and

\[(6.44) \quad |\tau [w_m(z, t, \lambda, \zeta, \tau) - w_m(z, t, \lambda, \tau)f_n(\zeta + \tau z_1)]| \leq \frac{A}{|\tau|} |\lambda|^c \exp(c^*B|\lambda t_0|)(\text{log}(\zeta + \tau z_1) + C_1). \]

**Proof.** The following argument is the same as in Proposition 4.2. We have, by Proposition 6.8,

\[
\sum_{n=0}^{m} |x'(\tau - \tau_\lambda)|^n w_h(z, t, \lambda, \tau)(\zeta + \tau z_1)^n / n! |
\leq \frac{A}{|\tau|} \sum_{n=0}^{m} B(\zeta + \tau z_1) / \tau^{n} (\sum_{\tau=\tau_0}^{\tau_1} |\lambda t_0|^r / |\tau|^{n+1}).
\]

If \(|(\zeta + \tau z_1)/\tau| < c^*\) and \(c^*B < 1/2\), the above series converges and we have (6.43). We have (6.44) by the same method.

**Remark 6.10.** Since \(w_h(z, t, \lambda, \tau) (h = m, n \geq -1)\) are holomorphic at \(\tau = 0\), it follows from the maximal principle of holomorphic functions and (6.41) that \(w_h(z, t, \lambda, \zeta, \tau) (h = m)\) are holomorphic at \(\tau = 0\). Since \(w_m(z, t, \lambda, \zeta, \tau) (n \geq -1)\) have a single pole at \(\tau = 0\), \(w_m(z, t, \lambda, \zeta, \tau)\) has a single pole at \(\tau = 0\) by (6.42).

We have obtained \(w_h(z, t, \lambda, \zeta, \tau)\) in (6.25). So we proceed to construction of \(W_h(z, t, \lambda, \zeta)\). Define

\[(6.45) \quad W_h(z, t, \lambda, \zeta) = \int_{\tau_1 = \zeta}^{\tau_1 = \zeta_1} w_h(z, t, \lambda, \zeta, \tau) d\tau \quad (0 \leq i \leq p), \]

where \(a_i |\lambda|^{a_i-a_1} < c_t < b_{i-1} |\lambda|^{a_{i-1}-a_1}\) and constants \(a_t\) and \(b_t\) are those in
Proposition 6.2, \( a_p = 0, b_{-1} = +\infty \). Put

\[ W^h(z, t, \lambda, \zeta) = W^h_0(z, t, \lambda, \zeta). \]  

Now we study the domain to which \( W^h(z, t, \lambda, \zeta) (0 \leq h \leq m) \) are holomorphically extensible as functions of \( \zeta \). So we often omit the other variables. We always assume \( (z, t, \lambda) \in \mathcal{A}_0, \mathcal{A}_0 = \{ \lambda \in C^1; |\lambda| \geq A_0 \}, X = \{(z, t); |z| \leq r_1, |t_0| \leq r_3, r_2 \leq |t| \leq r_3 \} \), and put

\[ (6.46) \quad W^h(z, t, \lambda, \zeta) = W^h_0(z, t, \lambda, \zeta). \]

for a \( C > 0 \), which is chosen suitably. Firstly we have from Proposition 6.9 and Remark 6.10.

**Proposition 6.11.**
(1) \( W^h_0(\zeta) \) is holomorphic in \( Z(i) \).
(2) \( W^h_0(\zeta) = 0 \) and \( W^h_0(\zeta) = a(\zeta)/\zeta + b(\zeta) \log \zeta \) in \( Z(p) \), where \( a(\zeta) \) and \( b(\zeta) \) are holomorphic.

**Proof.** Suppose that \( a_{i+1}|\lambda|^{a_{1+1}} < |r| < b_{i-1}|\lambda|^{a_{i-1}+1}, |\lambda| > |\lambda z_1| \) and \( |\lambda z_1| < c^*|\lambda|, c^* \) being that in Proposition 6.9. Then \( w(z, t, \lambda, \zeta, \tau) = a_i|\lambda|^{a_i-1}\zeta < b_{i-1}|\lambda|^{a_{i-1}-1} \), we have \( W^h_0(\zeta) \in \mathcal{O}(\zeta), Z^* = \{ \zeta; r|\zeta| < |\zeta| < (c^* - |\zeta|)|r| \}. \) So varying \( r \), we have (1) for a constant \( C > 0 \). Since \( w^h(z, t, \lambda, \zeta, \tau) (h = m) \) is holomorphic on \( \tau(p) \), \( W^h_0(\zeta) \equiv 0 \).

\[ W^m(z, t, \lambda, \zeta, \tau) \) has a single pole at \( \tau = 0 \) in \( \tau(p) \), that is, \( w^m(z, t, \lambda, \zeta, \tau) = (1/\tau) \sum_{n=-1}^{n=0} w^m(z, t, \lambda, \zeta, \tau) \), where \( \tilde{w}^m(z, t, \lambda, \zeta, \tau) \) (\( n \geq -1 \)) are holomorphic in \( \tau(p) \) (see Remark 6.10). Hence

\[ W^h_0(z, t, \lambda, \zeta) \equiv \int_{|\tau| = \epsilon \rho}^\infty w^m(z, t, \lambda, \zeta, \tau) d\tau = \Sigma_{n=-1}^{n=0} \tilde{w}^m(z, t, \lambda, \zeta, \tau) \]

which implies (2).

Put

\[ (6.49) \quad W^h_{i+1}(\zeta) = W^h_i(\zeta) - W^h_i(\zeta), \quad i = 0, 1, \ldots, \rho - 1. \]

It follows from Proposition 6.11 that \( W^h_{i+1}(\zeta) \) is holomorphic in \( Z_i, Z_i = \{ \zeta; a_i|\zeta| < |\zeta| < (C - |\zeta|)|b_i|\lambda|^{a_i-1} \} \), for small \( z_i \). We have by the deformation of the integration path to \( \partial(K_\tau^h(\eta)|\lambda|^{a_i-1}) \) (see (6.35)).

\[ W^h_i(z, t, \lambda, \zeta, \tau) \]

From (6.50) we have

**Proposition 6.12.** \( W^h_{i+1}(\zeta) \) is holomorphic on \( Z_{i+1} \) for small \( z_i, Z_{i+1} = \{ \zeta \in -z_i K^h_\tau(\eta)|\lambda|^{a_i-1}; |\zeta| < (C - |\zeta|)|b_i|\lambda|^{a_i-1} \} \).

Considering Propositions 6.11 and 6.12 and (6.49), we have
Proposition 6.13. \( W^h_\zeta(\zeta) \) \((i \neq p)\) has a holomorphic prolongation to \( \hat{Z}_t \),

\[
Z_t = \{ \zeta \in \mathbb{C} : |\zeta| < \epsilon, K^\beta_\gamma(\eta) \lambda^\gamma a_{i-1} \}
\]
\[
a_{i+1} |z_1| |\lambda|^{a_{i+1} - a_i} < |\zeta| < (C - |z_1|) b_{i-1} |\lambda|^{a_{i-1} - a_{i-1}} ,
\]
for small \( z_1 \). Moreover \( W^h_{p-1}(\zeta) \) \( (0 \leq h \leq m-1)\) are holomorphic at \( \zeta = 0 \).

Hence, by using the relation

\[
(6.52) \quad W^h(\zeta) = W^h(z) \quad \text{in} \quad \hat{Z}(0)
\]
\[
= W^h_{z,1}(\zeta) + W^h_{z,2}(\zeta) \quad \text{in} \quad \hat{Z}_{z,1} \cap \hat{Z}(1)
\]
\[
= W^h_{z,1}(\zeta) + W^h_{z,3}(\zeta) + W^h_{z}(\zeta) \quad \text{in} \quad \hat{Z}_{z,1} \cap \hat{Z}(2)
\]
\[
= \ldots \ldots
\]
\[
= W^h_{z,1}(\zeta) + W^h_{z,3}(\zeta) + W^h_{z,5}(\zeta) + \ldots + W^h_{z, p-1}(\zeta) + W^h_{z=1}(\zeta) + W^h_{z}(\zeta)
\]
\[
\text{in} \quad \hat{Z}_{z, p-1}
\]
we can prolonge \( W^h(\zeta) \) \( (0 \leq h \leq m)\) holomorphically. Thus we have

Proposition 6.14. There is a covering \( \hat{Z} \) of \( Z = \bigcup_{\zeta=0}^m Z_\zeta \) such that each \( W^h(\zeta) \) \( (0 \leq h \leq m)\) has a holomorphic prolongation to \( \hat{Z} \) as a function of \( \zeta \), \( W^h(\zeta) \) \((h \neq m)\) is holomorphic at \( \zeta = 0 \) in \( \hat{Z} \) and the singularity of \( W^m(\zeta) \) at \( \zeta = 0 \) is polar and logarithmic, that is, \( W^m(\zeta) = a(\zeta)/\zeta + b(\zeta) \log \zeta \) at \( \zeta = 0 \).

Define

\[
(6.53) \quad \hat{K}_\zeta^h(z, t, \lambda) = \int_{C_{\theta}^h} \exp(-\lambda \varepsilon \zeta) W^h(z, t, \lambda, \zeta) d\zeta ,
\]
where \( C_{\theta}^h = \{ \zeta = d^{-1} e^{i(\theta + 2\pi n)} \lambda^{1-\alpha_1} ; 0 \leq s \leq 1 \} \), \( a_0 |z_1| \leq d_{-1} \). We have

Proposition 6.15. The following estimates hold:

\[
(6.54) \quad |\hat{K}_\zeta^h(z, t, \lambda)| \leq A(1 + |\lambda|)^N \exp \left( d_{-1} |\lambda| + c^* B |\lambda_0| \right) \quad \text{for} \quad |\lambda| \geq A_0 ,
\]
and if \( |\arg \lambda + \theta| < \pi/2 \),

\[
(6.55) \quad |\hat{K}_\zeta^h(z, t, \lambda)| \leq A(1 + |\lambda|)^N \exp \left( a_0 |\lambda z_1| + c^* B |\lambda_0| \right) ,
\]
where \( c^* \) and \( B \) are those in Proposition 6.9.

Proof. The estimate (6.54) follows from Proposition 6.9. We can deform the path \( C_{\theta}^h \) to \( C_{\theta}' \), starting at \( \zeta = d_{-1} e^{i\theta} \lambda^{1-\alpha_1} \), going to \( a_0 |z_1| e^{i\theta} \lambda^{1-\alpha_1} \), enclosing the origin \( \zeta = 0 \) once on \( |\zeta| = a_0 |z_1| \lambda^{1-\alpha_1} \) and going from \( a_0 |z_1| e^{i(\theta + 2\pi n)} \lambda^{1-\alpha_1} \) to \( d_{-1} e^{i(\theta + 2\pi n)} \lambda^{1-\alpha_1} \). We have (6.55) by this deformation.
Now we can define \( K^h(w, z, t) \), \( 0 \leq h \leq m \), (see (6.9), (6.10) and (6.53))

\[
K^h_w(w, z, t) = \int_{d_0}^{e^{-\phi}} \exp(-\lambda w) K^h(z, t, \lambda) d\lambda, \quad |\phi + \theta| < \frac{\pi}{2},
\]

which depends on \( \theta \). We have from Proposition 6.15,

**Proposition 6.16.** \( K^h_w(w, z, t) \) is holomorphic in \( \{(w, z, t); |\arg w - \theta| < \pi, \quad |w| > a_0 |z_1| + c^* B |t_0|\} \).

**Proposition 6.17.** If \( c^* > 0 \) in Proposition 6.15 is small, then the following identities hold:

\[
L(z, \partial_0)K^h_0(t_0 - z_0, z, t) = \frac{\partial_{h_{-1}}}{(2\pi i)^n} \frac{1}{t_0 - z_0} \prod_{i=1}^{n-1} \frac{1}{t_i - z_i},
\]

\[
(\partial_i)K^h_0(t_0 - z_0, z, t) = \frac{\partial_{h_{-1}}}{(2\pi i)^n} \frac{1}{t_0 - z_0} \prod_{i=1}^{n-1} \frac{1}{t_i - z_i} \quad \text{for} \quad 0 \leq k \leq m - 1,
\]

where \( \equiv \) means modulo holomorphic functions on \( X \).

**Proof.** By repeating the same method as in the proof of Proposition 4.5, we have

\[
L(z, \partial_0)K^h_0(t_0 - z_0, z, t)
= \int_{d_0}^{e^{-\phi}} \exp(-\lambda(t_0 - z_0)) d\lambda \int_{c_0(\theta)}^{e^{-\phi}} \exp(-\lambda \zeta) \frac{-\partial_{h_{-1}}}{(2\pi i)^n} \frac{1}{t_0 - z_0} \prod_{i=1}^{n-1} \frac{1}{t_i - z_i} d\zeta
+ \int_{d_0}^{e^{-\phi}} \exp(-\lambda(t_0 - z_0) - \lambda d_{-1} e^{i\theta}) \tilde{K}^h(z, t, \lambda) d\lambda,
\]

where \( |\tilde{K}^h(z, t, \lambda)| \leq C(1 + |\lambda|)^N \exp(c^* B |\lambda_0|) \) for some \( N \). If \( c^* > 0 \) is small such as \( d_{-1} > c^* B |t_0| \), then, by putting \( \phi = -\theta \) in (6.56),

\[
\int_{d_0}^{e^{-\phi}} \exp(-\lambda w - \lambda d_{-1} e^{i\theta}) \tilde{K}^h(z, t, \lambda) d\lambda
\]

is holomorphic at \( w = 0 \). It is easy to get (6.58).

Define, putting \( \theta = -\pi \),

\[
K^h_w(w, z, t) = K^h_x(w, z, t),
\]

and \( d_0 = \sin^{-1}(c^* B) \), where \( c^* > 0 \) is small. Now let \( u(z) \in \mathcal{O}(\mathcal{O}(\theta)) \) be a solution of (6.1) with \( f(z) \in \mathcal{O}(\mathcal{O}(\theta)) \), \( \theta_d > d_0 \). Define

\[
u_z(z) = \sum_{h=0}^{m} u_z^h = \sum_{h=0}^{m-1} \int_{T^0 \times T^*} K^h(t_0 - z_0, z, t) u^h(t_0, 0, t^*) dt_0 dt^*
+ \int_{T^0 \times T^*} K^m(t_0 - z_0, z, t) f(t_0, t') dt_0 dt',
\]
where \( T_\theta = T_\theta(a, b) \) and \( u^*(t_0, 0, t^*) = \partial^1_t u(t_0, 0, t^*) \). The formula (6.60) is an integral representation of \( u(z) \) in (6.1). We have from Proposition 6.17.

**Theorem 6.18.** \( u_\theta(z) \) defined by (6.60) satisfies

\[
L(z, \partial_z)u_{\theta}(z) = f(z),
\]

where \( \equiv \) means modulo holomorphic functions at \( z = 0 \), and \( u(z) - u_{\theta}(z) = v(z) \in \mathcal{O}(U) \) in a neighbourhood of the origin.

**Proof.** We have by the method used to show Proposition 4.5

\[
L(z, \partial_z)u_{\theta}(z) = \frac{1}{(2\pi i)^{n+1}} \int_{t_0 - T^*} \frac{f(t)}{t_0 - z} \prod_{t_k} \frac{1}{t_k - z} dt_0 dt',
\]

This means (6.61). We have (6.62) from (6.58). It follows from the uniqueness of Cauchy problem that \( u(z) - u_{\theta}(z) = v(z) \in \mathcal{O}(U) \) in a neighbourhood of the origin.

**Remark 6.19.** We can show that if \( |\theta - \theta'| \) is small then \( K^h_\theta(w, z, t) - K^h_\theta(w, z, t) \) is holomorphic in a neighbourhood of \( w = 0 \). So the representation (6.60) is holomorphically extensible to wider domains, which will be done by replacing \( K_\theta(w, z, t) \) by \( K_\theta(w, z, t) \).

We investigate \( \hat{K^h}_\varphi(z, t, \lambda) = \hat{K^h}_\varphi(z, t, \lambda) \) more precisely, by using Proposition 6.7. So in the sequel we restrict \( (z, t, \lambda) \) to the set

\[
\hat{X}_\delta = X' \times \hat{A}_\delta, \quad X' = \{ (z, t, \lambda); (z, t) \in X, |z - z_0| < \varepsilon_1 \}.
\]

The following arguments are similar to that in [12]. Firstly we decompose integration path \( C_\theta = C_\theta(-\pi) \) in (6.53), and secondly according to the decomposition of \( C_\theta \), decompose \( \hat{K^h}_\varphi(z, t, \lambda) = \sum_{i=1}^p \hat{K^h}_\varphi(z, t, \lambda) \). We investigate each \( \hat{K^h}_\varphi(z, t, \lambda) \). So we define some paths in \( \zeta \)-space. For a path \( C = [\zeta(s); 0 \leq s \leq 1] \) and \( a \in C \), put \( C_a = \{ a_\zeta(s) \mid 0 \leq s \leq 1 \} \). Put \( A_i = \{ \zeta(s) = \zeta_i; 0 \leq s \leq 1 \} \) and \( B_i = \{ \zeta_i e^{-i\pi a_1^e+2\pi si}; 0 \leq s \leq 1 \} \). The path \( C_\theta \) and \( C_p \) were not used in [12].
We note that the singularity of $W_h(z, t, \lambda, \zeta)$ with respect to $\zeta$ are in $(\cup_{i=1}^{\infty} \lambda^{-1-a_i}K_{x_i}^*(\eta/2)) \cup \{\zeta=0\}$. Define

\begin{equation}
\hat{K}_t(z, t, \lambda) = \int_{C_t} \exp(-\lambda^{a_i}\zeta) W_h(z, t, \lambda, \zeta) d\zeta
\end{equation}

Let us deform the path $\lambda^{a_i-a_i}B_i$ to another. We give

**Lemma 6.20.** The path $\lambda^{a_i-a_i}B_i$ can be deformed homotopically to $B_i^*$ such that: $B_i^* = \lambda^{a_i-a_i}B_i + C_{i+1} + \lambda^{a_i-a_i}B_i'$, where $B_i'$ and $B_i''$ are independent of $\lambda$, contained in $\{\zeta; d_i \leq |\zeta| \leq c_i\}$ and $(B_i' \cup B_i'') \cap S_i = \emptyset$, and

\begin{equation}
\int_{\lambda^{a_i-a_i}B_i} \exp(-\lambda^{a_i}\zeta) W_h(z, t, \lambda, \zeta) d\zeta
\end{equation}

Proof. As we remarked, the singularities inside of $C_i$ of $W_h(z, t, \lambda, \zeta)$ are in $(\cup_{i=1}^{\infty} \lambda^{-1-a_i}K_{x_i}^*(\eta/2)) \cup \{\zeta=0\}$ and the set $(\cup_{i=1}^{\infty} \lambda^{-1-a_i}K_{x_i}^*(\eta/2)) \cup \{\zeta=0\}$ are inside of $C_{i+1}$. So we can deform $B_i$ so that $B_i'$ and $B_i''$ encloses $-z, K_{x_i}^*(\eta/2)$. From Proposition 6.7, we can take $B_i'$ and $B_i''$ so that $(B_i' \cup B_i'') \cap S_i = \emptyset$ (see Fig 6.2).
Fig. 6.2.

The singularities of $W^h(z, t, \lambda, \zeta)$ inside of $C_1$ are in the parts of oblique lines in Fig. 6.2.

Thus we have

**Proposition 6.21.** $R^h(z, t, \lambda)$ is represented in the following form:

$$
(6.67) \quad R^h(z, t, \lambda) = \sum_{n=0}^{m-1} \left( \int_{A_0} + \int_{c_1} \exp(-\lambda^{\alpha_1} \zeta) W^h(z, t, \lambda, \zeta) d\zeta \right)
$$

$$
+ \int_{c^*} \exp(-\lambda^{\alpha_1} \zeta) W^h(z, t, \lambda, \zeta) d\zeta,
$$

where if $h=m$ the last term integrated on $C_p$ does not appear.

**Proof.** We have

$$
R^h(z, t, \lambda) = \int_{c_0} \exp(-\lambda^{\alpha_1} \zeta) W^h(z, t, \lambda, \zeta) d\zeta
$$

$$
= \left( \int_{A_0} + \int_{c_1} \exp(-\lambda^{\alpha_1} \zeta) W^h(z, t, \lambda, \zeta) d\zeta \right)
\int_{c^*} \exp(-\lambda^{\alpha_1} \zeta) W^h(z, t, \lambda, \zeta) d\zeta.
$$

Since

$$
\int_{c_1} \exp(-\lambda^{\alpha_1} \zeta) W^h(z, t, \lambda, \zeta) d\zeta = \left( \int_{B_1} + \int_{c_1} + \int_{c^*} \right) \exp(-\lambda^{\alpha_1} \zeta) W^h(z, t, \lambda, \zeta) d\zeta
$$

and
we have \((6.67)\). If \(h \neq m\), \(W^h(z, t, \lambda, \zeta)\) is holomorphic at \(\zeta = 0\), so the last term in \((6.67)\) vanishes.

For our purpose we further decompose \(\tilde{K}^h(z, t, \lambda)\). In order to do so we need several lemmas concerning the paths \(A_i, B'_i\) and \(B''_i\). The following lemmas are the same as in [12] and the proofs are not so difficult. So we omit them.

**Lemma 6.22.** Let \(\zeta \in A_i (0 \leq i \leq p - 1)\) and \(\arg \lambda = \pi\). Then there is a \(c > 0\) such that \(\Re \lambda^{\alpha_i} \zeta \geq c |\lambda|^{\alpha_i}\).

**Lemma 6.23.** Let \(K\) be a compact set in \(C^1\) and \(K \cap \bar{S}_i = \emptyset\). If the diameter of \(K\) is sufficiently small, then there are \(c_K > 0\) and \(\phi_K\) with \(|\phi_K - \pi| < \pi/2\alpha_i\) such that \(\Re \lambda^{\alpha_i} \zeta \geq c_K |\lambda|^{\alpha_i}\) for \(\zeta \in \lambda^{\alpha_i - 1} K\) and \(\lambda\) with \(\arg \lambda = \phi_K\).

By Lemma 6.23 we can decompose the paths \(B'_i\) and \(B''_i\) in the following way.

**Proposition 6.24.** There are paths \(B_{i, s}\) \((1 \leq s \leq r_i)\), constants \(\psi_{i, s}\) with \(|\psi_{i, s} - \pi| < \pi/2\alpha_i\) and \(c > 0\), which are all independent of \(\lambda\) such that \(B_i = \sum B_{i, s}\) and \(B''_i = \sum B_{i, s}\), and \(\Re \lambda^{\alpha_i} \zeta \geq c |\lambda|^{\alpha_i}\) for \(\zeta \in \lambda^{\alpha_i - 1} B_{i, s}\) and \(\lambda\) with \(\arg \lambda = \psi_{i, s}\).

Define, by using \(A_i (0 \leq i \leq p - 1)\), \(B_{i, s}\), in Proposition 6.24 and \(C_p\),

\[
(6.68) \quad \tilde{K}_{i, s}^h(z, t, \lambda) = \left(\int_{A_i} + \int_{-e^{2\pi i} A_i}\right) \exp(-\lambda^{\alpha_i} \zeta) W^h(z, t, \lambda, \zeta) d\zeta,
\]

\[
(6.69) \quad \tilde{K}_{i, s}^h(z, t, \lambda) = \int_{B_{i, s}} \exp(-\lambda^{\alpha_i} \zeta) W^h(z, t, \lambda, \zeta) d\zeta, \quad B_{i, s}(\lambda) = \lambda^{\alpha_i - 1} B_{i, s},
\]

and

\[
(6.70) \quad \tilde{K}_{i, s}^h(z, t, \lambda) = \int_{C_p} \exp(-\lambda^{\alpha_i} \zeta) W^h(z, t, \lambda, \zeta) d\zeta.
\]

Then we have

\[
(6.71) \quad \tilde{K}^h(z, t, \lambda) = \sum_{s=0}^{p} \sum_{i=0}^{r_i} \tilde{K}_{i, s}^h(z, t, \lambda),
\]

where \(r_p = 0\) and \(\tilde{K}_{i, s}^h(z, t, \lambda) = 0\) \((h \neq m)\). \(\tilde{K}_{i, s}^h(z, t, \lambda) (0 \leq i \leq p, 0 \leq s \leq r_i)\) are holomorphic on \(\mathcal{L}_s^h, \mathcal{L}_s^h = \{\lambda; |\lambda| \geq A_s\}\), as functions of \(\lambda\) and holomorphic on \(X'\) as functions of \((z, t)\). As for the estimates of them we have
Proposition 6.25. The following estimates hold for \((z, t, \lambda) \in \tilde{X}_h^p:\)

1. for each \(K_h^p(z, t, \lambda)\) for \(0 \leq i \leq p-1\)

\[
|K_h^p(z, t, \lambda)| \leq A \exp \left( C |\lambda|^{a_1-i} + (\sin \delta_0) |\lambda t_0| \right) \text{ on } \tilde{A}_h^p,
\]

\[
|K_h^p(z, t, \lambda)| \leq A \exp \left( -c |\lambda|^{a_1-i} + (\sin \delta_0) |\lambda t_0| \right) \text{ on } \{ \lambda \in \tilde{A}_h^p; \arg \lambda = \pi \}.
\]

2. for each \(K_h^p(z, t, \lambda)\) for \(0 \leq i \leq p-1, s = 0\)

\[
|K_h^p(z, t, \lambda)| \leq A \exp \left( C |\lambda|^{a_1+i} + (\sin \delta_0) |\lambda t_0| \right) \text{ on } \tilde{A}_h^p,
\]

\[
|K_h^p(z, t, \lambda)| \leq A \exp \left( -c |\lambda|^{a_1+i} + c |\lambda|^{a_1} |\lambda t_0| \right) \text{ on } \{ \lambda \in \tilde{A}_h^p; \arg \lambda = \phi_{i,s} \},
\]

where \(\delta_0 = \sin^{-1}(c \lambda)B\) and all constants are positive.

Proof. The estimates (6.72), (6.74) and (6.76) are obvious. The estimates (6.73) and (6.77) follow from Proposition 6.24. It remains to show (6.75). It follows from Proposition 6.11-(2) that

\[
K_h^p(z, t, \lambda) = \int_{C_p} \exp \left( -\lambda a_1 \zeta \right) W^m(z, t, \lambda, \zeta) d\zeta
\]

\[
= \frac{1}{2\pi i} \int_{C_p} \exp \left( -\lambda a_1 \zeta \right) \left[ \frac{a(\zeta, \lambda)}{\zeta} + b(\zeta, \lambda) \log \zeta \right] d\zeta
\]

\[
= a(0, \lambda) + \int_0^{d_{p-1} e^{-i\pi a_{p-1}} a_{p-1} a_1} \exp \left( -\lambda a_1 \zeta \right) b(\zeta, \lambda) d\zeta,
\]

where we deform \(C_p\) to the path \(C'_p, C'_p = (\zeta(s) = (1-2s)d_{p-1} e^{-i\pi a_{p-1}} a_{p-1} a_1\) \((0 \leq s \leq 1/2), \zeta(s) = (2s-1)d_{p-1} e^{-i\pi a_{p-1}} a_{p-1} a_1 \) \((1/2 \leq s \leq 1))\), and use

\[
\frac{1}{2\pi i} \int_{C_p} \exp \left( -\lambda a_1 \zeta \right) b(\zeta, \lambda) \log \zeta d\zeta = \int_0^{d_{p-1} e^{-i\pi a_{p-1}} a_{p-1} a_1} \exp \left( -\lambda a_1 \zeta \right) b(\zeta, \lambda) d\zeta.
\]

If \(|\arg \lambda - \pi| < \pi/2a_{p-1}, |exp(-\lambda a_1 \zeta)|\) is bounded on \(C'_p\). Thus we have (6.75).

We divide \(u_h^a(z)\), by using \(K_h^p(z, t, \lambda)\), into the sum of \(u_{h_{x,t,s}}^a(z)\). Put

\[
K_h^p(w, z, t) = \int_{\tilde{A}_h^p} \exp \left( -\lambda w \right) K_h^p(z, t, \lambda) d\lambda,
\]

\[
u_{h_{x,t,s}}^a(z) = \int_{T_0 \times T_0} K_h^p(t_0 - z_0, z, t^s) u_h^a(t_0, 0, t^s) dt_0 dt^s
\]

for \(0 \leq h \leq m-1\) and

\[
u_{m_{x,t,s}}^a(z) = \int_{T_0 \times T_0} K_h^p(t_0 - z_0, z, t) f(t) dt.
\]
Thus we have

\[ u(z) = \sum_{(i, s)} u_{i, s}^h(z) + v(z), \quad v(z) \in \mathcal{O}(U), \]

where \( U = U_0 \times U', U_0 = \{ z_0 \in \mathbb{C}^n; |z_0| \leq r \} \) and \( U' = \{ z' \in \mathbb{C}^n; |z_1 - z_1| < \varepsilon_1, |z'| \leq r \} \).

In the rest of this section \( U \) means that defined above, where \( r \) is small if necessary, and we consider a solution \( u(z) \) of (6.1) and \( f(z) \) satisfying some growth conditions:

\[ (6.83) \]

where \( U = U_0 \times U', U_0 = \{ z_0 \in \mathbb{C}^n; |z_0| \leq r \} \; \text{and} \; U' = \{ z' \in \mathbb{C}^n; |z'| \leq r \} \).

Proposition 6.26. Assume (6.2), (6.4) and (6.83).

1. \( u_{i, s}^h(z) \) \( (i \neq 0, (i, s) \neq (1, 0)) \) are holomorphically extensible to \( U(\theta_0 - \varepsilon_0) \) and

\[ (6.84) \]

in \( z \in U(\theta') \) with any \( \theta' < \theta_0 - \varepsilon_0 \), where \( \gamma_i = \sigma_{p-1} - 1 = \alpha_i/(1 - \alpha_i) \).

2. \( u_{i, s}^h(z) \) \( (i = 0 \text{ or } (i, s) = (1, 0)) \) are holomorphic at the origin.

Proof. (1) It follows from (6.72), (6.74) and (6.76) that if \( i \neq 0 \) or \( (i, s) \neq (1, 0) \), \( |K_{i, s}^h(w, z, t)| \leq A \exp(-c \cdot |z_i|^{-\gamma_i}) \) for some \( 0 < \alpha < 1 \) on \( \Lambda_0^\varepsilon \). So we have the assertion from (6.83)' and Proposition 5.2-(1).

(2) Suppose \( i = 0 \) or \( (i, s) = (1, 0) \). By (6.73) \( |K_{i, s}^h(w, z, t)| \leq A \exp(-c \cdot |\lambda| + (\sin \delta_0) |\lambda_0|) \) on \( \lambda \in \Lambda_0^\varepsilon; \arg \lambda = \pi \). So \( K_{i, s}^h(w, z, t) \) is holomorphic at \( w = 0 \). This means that \( u_{i, s}^h(z) \) is holomorphic at \( z = 0 \).

Now we use the estimates (6.73), (6.75) and (6.77) on the line \( \{ \lambda; \arg \lambda = \phi_{i, s} \} \), where \( \phi_{i, s} = \pi \). Put

\[ (6.85) \]

We obtain the asymptotic expansion of \( u_{i, s}^h(z) \).

Proposition 6.27. Assume the same conditions as in Proposition 6.26 and \( \theta_0 > \theta + \varepsilon_0, \varepsilon_1 > \delta_0 \). Then \( u_{i, s}^h(z) \) \( (i \neq p - 1) \) have the \( \gamma_{i-1} \)-asymptotic expansion with respect to \( z_0 \) with \( |z_0|; |z_0 + \phi_{i, s} - \pi| < \pi/2 \) in \( U \). If \( h' \) is small, \( u_{i, s}^{h, p-1, s}(z) \) have the \( \gamma_{p-1} \)-asymptotic expansion with respect to \( z_0 \) with \( |z_0|; |z_0 + \phi_{i, s} - \pi| < \pi/2 \) in \( U \).

Proof. We apply Proposition 5.2 to \( u_{i, s}^h(z) \). The bounds (6.73) or (6.77)
holds for \((h, i, s)\neq (m, p, 0)\). By the assumptions \((-\phi_{t, s}+(\pi/2)-\varepsilon_0, \phi_{t, s}+(3\pi/2)-\varepsilon_0)\subseteq (-\theta_0, \theta_0)\). So we have the \(\gamma\)-asymptotic expansion by Proposition 5.2-(2). Since \(\alpha_i > \alpha_{i-1} \quad (i \neq p-1)\), \(h'\) is not necessarily small for \(i \neq p-1\). For \((h, i, s) = (m, p, 0)\) the bounds (6.75) holds. In this case we have the \(\gamma_{p-1}\)-asymptotic by Proposition 5.2-(3).

We note that since \(\gamma = \gamma_{p-1} \leq \gamma_1\), we can say that there is an \(h'_0\) such that if \(0 < h' < h'_0\) in (6.83), then \(u_{h', s, t, i}(z)\) has the \(\gamma\)-asymptotic expansion with respect to \(z_0\) in \(\{\pi/2 < \arg z_0 + \phi_{t, s} < 3\pi/2\}\). We note that from the condition \(|\phi_{t, s} - \pi| < \pi/2\alpha_t\) there are \(\phi_{t, s}\) and \(\kappa_t\) such that \(|\phi_{t, s}| < \pi/2\kappa_t < \pi/2\gamma_t\) and \(u_{h', s, t, i}(z)\) has the \(\gamma\)-asymptotic expansion with respect to \(z_0\) on \(\arg z_0 = \phi_{t, s}\). Thus, by using Propositions 2.8 and 2.10, we have

**Theorem 6.28.** Assume (6.2). Let \(u(z) \in O_{1\{1\}, h'}(\Omega(\theta_0))\), \(\gamma = \sigma_{p-1} - 1\), be a solution of \(L(z, \partial_z)u(z) = f(z) \in \text{Asy}_{1\{1\}}(\Omega(\theta_0))\). Then there are positive constants \(H\) and \(\theta\) with \(0 < \theta < \pi/2\gamma + \pi\) such that, if \(\theta > \theta\) and \(h' < H\), \(u(z) \in \text{Asy}_{1\{1\}}(\Omega(\theta))\), where \(\theta = \theta'(h')\) with \(\lim_{h' \to h} \theta'(h') = \theta_0\).

**Proof.** It follows from the assumption (6.2) that (1.14) holds. So we may assume (1.14) holds at \(z = 0\) and \(\xi' = (1, 0, \ldots, 0)\), that is, (6.4) holds. Put \(\theta = (\theta + \pi/2\gamma + \pi)/2\). Obviously \(\pi/2\gamma + \pi > \theta\) by (6.85). Choose \(\delta_0\) and \(\varepsilon_0\) with \(0 < \delta_0 < \varepsilon_0 < \theta - \theta\) and fix them. Suppose \(\theta > \theta > \theta + \varepsilon_0\). Then it follows from Proposition 6.27 that if \(0 < h' < h_0\), \(u_{h', s, t, i}(z)\) has the \(\gamma\)-asymptotic expansion with respect to \(z_0\) on \(\{\arg z_0 = \phi_{t, s}\}\) in an open set \(U, \Omega \supset U \supset \emptyset\). It follows from Proposition 2.10 that if \(0 < h' < \min(h_0, h_0) = H\), \(h_0\) being that in Proposition 2.10, \(u(z)\) has the \(\gamma\)-asymptotic expansion in \(U(\theta')\) for some \(\theta' = \theta'(h')\) with \(\lim_{h' \to h} \theta'(h') = \theta_0\). Hence, from Proposition 2.8, \(u(z)\) has the \(\gamma\)-asymptotic expansion in \(\Omega(\theta')\).

**§7. Proof of Theorems and Estimates**

In §7 we give the proof of Theorems 1.13, 1.5 and 1.7, and finally show Propositions 4.1 and 6.8 which concern with estimates of functions and are not yet shown. For these purposes the method of majorant power series is available. So we summarize what we need. Let \(A(z) = \sum A_\alpha z^\alpha\) and \(B(z) = \sum B_\alpha z^\alpha\) be formal power series, where \(\alpha = (\alpha_0, \alpha_1, \ldots, \alpha_n) = (\alpha_0, \alpha') \in \mathbb{Z}^{n+1}\). Then \(A(z) > 0\) means \(A_\alpha > 0\) and \(A(z) < B(z)\) means \(|A_\alpha| < B_\alpha\) for all multi-indices \(\alpha\). We state elementary properties of majorant power series without the proof, which will be often used. For the proof we refer to [2], [5] and [15].

**Lemma 7.1 (Wagschal).** Let \(\Theta(s)\) be a formal power series of one variable \(s\) such that \(\Theta(s) > 0\) and
Then for derivatives $\Theta^{(j)}(s) = (d/ds)^j \Theta(s)$ ($j = 0, 1, \ldots$) we have

\begin{equation}
(R' - s)\Theta^{(j)}(s) \gg 0, \quad R'\Theta^{(j+1)}(s) \gg \Theta^{(j)}(s)
\end{equation}

and

\begin{equation}
(R_0 - s)^{-1} \Theta^{(j)}(s) \ll (R_0 - R')^{-1} \Theta^{(j)}(s) \quad (R_0 > R').
\end{equation}

**Lemma 7.2** (Wagschal). Let $\Theta(s)$ be a formal power series of one variable $s$ such that $\Theta(s) \gg 0$ and $(R' - s)\Theta(s) \gg 0$. Let $M(z, \partial_z)$ be a linear partial differential operator of order $m$ with the coefficients holomorphic in $\{|z| \leq R_0\}$, $R' < R_0$. Then

\begin{equation}
M(z, \partial_z) \Theta(s) \ll A\Theta^{(m)}(s), \quad s = z_0 + z_1 + \cdots + z_n,
\end{equation}

for a constant $A$ which is independent of $\Theta(s)$.

Now we proceed to show Theorem 1.13. Firstly we have

**Proposition 7.3.** Assume $L(z, \partial_z)$ satisfies the conditions (1.17)-(a), (b), (c) and put $\gamma = \sigma_{p-1} - 1$. Let $f(z) \in \text{Asy}_{1\varepsilon}(\Theta(\theta_0))$ with $0 < \kappa \leq \gamma$ and $0 < \theta_0 \leq \pi/2\alpha$. Then there exists a function $u(z) \in \text{Asy}_{1\varepsilon}(\Theta(\theta_0))$ such that $(L(z, \partial_z)u(z) - f(z)) \sim 0$ as a function in $\text{Asy}_{1\varepsilon}(\Theta(\theta_0))$.

**Proof.** From Remark 1.12, $L(z, \partial_z)$ is written in the form

\begin{equation}
L(z, \partial_z) = a_{k, p-1} s(z)(\partial_z)^{k-1} + \sum_{(k, l, j) \in \{k \in \mathbb{N}, l \leq k\}} z_0^{(k, l, j)} a_{k, l, j}(z, \partial_z)^{k-1},
\end{equation}

where $k - d_{k, l, j} = k_{p-1}$. Let $f(z) \sim \sum_{n=0}^\infty f_n(z') z_0^n/n!$, $f_n(z') \in \Theta(\partial')$, and $u(z) \sim \sum_{n=0}^\infty u_n(z') z_0^n/n!$. Then $u_n(z') (n \geq k_{p-1})$ are determined by

\begin{equation}
a_{k, p-1, 0}(s') u_n(z') = -\sum_{j = 0}^{(n-k_{p-1}-j)} \frac{(n-k_{p-1}-j)!}{(n-k_{p-1}-j)!} a_{k, l, j}(z', \partial') u_r(z') + f_{n-k_{p-1}-j}(z').
\end{equation}

We show, by induction,

\begin{equation}
u_n(z') \ll AB^n \theta^{(n-k_{p-1})/2} \cdot \theta^{(n-k_{p-1})/2}.
\end{equation}

where $\theta(s) = (R' - s)^{-1}$, $s = z_1 + z_2 + \cdots + z_n$.

By the assumption $f_n(z') \ll AB^n \theta^{(n-k_{p-1})/2}$. So (7.7) is obvious for $n = k_{p-1}$. Assume (7.7) holds for $r$ with $r < n$. Then

\begin{equation}
\frac{(n-k_{p-1}-j)!}{(n-k_{p-1}-j)!} a_{k, l, j}(z', \partial') u_r(z') \ll AB^n \theta^{(n-k_{p-1})/2} \cdot \theta^{(n-k_{p-1})/2}.
\end{equation}
Since \( l+j \geq \sigma_{k-1}(k-k_{p-1}) = (r+1)(k-k_{p-1}) \geq (k+1)(k-k_{p-1}) \) for \( k \geq k_{p-1}, [(r-k_{p-1}+k-l-j)/k] \leq [(n-k_{p-1})/k] + k_{p-1} - k. \) Hence

\[
(7.9) \quad \frac{(n-k_{p-1})!}{(n-k_{p-1}-j)!} a_{k, i}(z', \partial') u_{r}(z')
\]

\[
\ll AMB^* C^j \pi_{1}^* (n-k_{p-1})^{r+s+k-1}(s)
\]

\[
\ll AMB^* D^j \pi_{1}^* (n-k_{p-1})^{r+s+k-1}(s)
\]

Thus we have (7.7). Since \( 0 < \theta \leq \pi/2 \), it follows from Proposition 2.1 that there is a \( u(z) \in \text{Asy}_{k}([U/2\varepsilon]) \) in a neighbourhood \( U \) such that \( u(z) \sim \sum_{n=k_{p-1}}^{\infty} u_{n}(z') (z_{0})^{n} \) and \( (L(z, \partial_{z}) u(z) - f(z)) \sim 0 \) in \( \text{Asy}_{k}([U/\theta]) \).

\textit{Proof of Theorem 1.13.} It follows from Proposition 7.3 that there is a \( u(z) \in \text{Asy}_{k}([\Omega(\theta)]) \) such that \( g(z) = (L(z, \partial_{z}) u(z) - f(z)) \sim 0 \) as a function in \( \text{Asy}_{k}([\Omega(\theta)]) \). Define, as in Proposition 2.13,

\[
(7.10) \quad \tilde{u}(z) = \int_{0}^{\tau} \frac{u(t, z')}{z_{0} - t_{0}} dt_{0}.
\]

We have, by integrations by parts, for multi-index \( \alpha \) with \( \alpha_{0} \leq k_{p-1} \)

\[
(7.11) \quad \partial_{z}^{\alpha} u(z) = (-1)^{\alpha_{0}} \alpha_{0}! \int_{0}^{\tau} \partial_{z}^{\alpha_{0}} u(t, z')/(z_{0} - t_{0})^{\alpha_{0}+1} dt_{0}
\]

\[
= \int_{0}^{\tau} \{ \partial_{z}^{\alpha_{0}} \partial_{z}^{\alpha_{0}} u(t, z')/(z_{0} - t_{0}) \} dt_{0} + g_{1}(z),
\]

where \( g_{1}(z) \in \mathcal{O}(U), \) \( U(|z| \leq r), \) is determined by the values of the derivatives of \( u(t, z') \) at \( t_{0} = 0. \) Let \( A(z) \) be holomorphic in \( \Omega \) and put

\[
(7.12) \quad g_{2}(z) = \int_{0}^{\tau} (A(z_{0}, z') - A(t_{0}, z')) (\partial_{z}^{\alpha_{0}} \partial_{z}^{\alpha_{0}} u(t_{0}, z')/(z_{0} - t_{0})) dt_{0}.
\]

Then we have

\[
(7.13) \quad g_{3}(z) = \int_{0}^{\tau} \left( \int_{0}^{1} (\partial_{z} A(s z_{0} + (1-s)t_{0}, z') ds \right) (\partial_{z}^{\alpha_{0}} \partial_{z}^{\alpha_{0}} u(t_{0}, z')/(z_{0} - t_{0})) dt_{0}
\]

and \( g_{3}(z) \in \mathcal{O}(U). \) Hence we have

\[
(7.14) \quad A(z) \partial_{z} \tilde{u}(z) = \int_{0}^{\tau} A(t_{0}, z') (\partial_{z}^{\alpha_{0}} \partial_{z}^{\alpha_{0}} u(t_{0}, z')/(z_{0} - t_{0})) dt_{0} + g_{3}(z),
\]

where \( g_{3}(z) \in \mathcal{O}(U). \) Thus there is a \( g_{4}(z) \in \mathcal{O}(U) \) such that

\[
(7.15) \quad L(z, \partial_{z}) \tilde{u}(z) = \int_{0}^{\tau} (f(t_{0}, z')/(z_{0} - t_{0})) dt_{0} + g_{4}(z) + g_{0}(z)
\]

\[
= \int_{0}^{\tau} (f(t_{0}, z')/(z_{0} - t_{0})) dt_{0} + g_{0}(z) + g_{5}(z).
\]
It follows from the proof of Proposition 2.13 that 
\[ \tilde{f}(z) - f(z) \log z_0, \tilde{g}(z) - g(z) \log z_0 \in \text{Asy}_{\theta_0}(U(\theta_0)) \]. Since \( g(z) \sim 0 \) in \( \text{Asy}_{\theta_0}(U(\theta_0)) \), \( \tilde{g}(z) \in \text{Asy}_{\theta_0}(U(\theta_0)) \). This means
\[ L(z, \partial_z)u(z) = f(z) - \tilde{f}(z) + \tilde{g}(z) - g(z) = \text{Asy}_{\theta_0}(U(\theta_0)). \]

Now we show Theorems 1.5 and 1.7. Let \( u(z) \in \mathcal{O}(\mathcal{Q}(\theta_0)) \) be a solution of
\[
L(z, \partial_z)u(z) = f(z).
\]

**Proof of Theorem 1.5.** We use Theorems 1.11 and 6.28. The positive constants \( H \) and \( \Theta \) are those in Theorem 6.28. Suppose that \( f(z) \in \text{Asy}_{\theta_0}(\mathcal{Q}(\theta_0)) \) in (7.16). Since \( a_{p-1} = 0, a_{p-1,0} = 0 \), \( \alpha_0 = \beta_0 = 0 \), we may assume that \( a_{p-1,0} = 0, \alpha_0 = \beta_0 = 0 \). Hence, (1.17) holds and \( \theta_0 < \pi/2 \). By Proposition 2.11, we can decompose \( u(z) \) for \( h > 0 \)
\[
u_i(z) = \sum_{i=1}^{l} u_i(z), \quad u_i(z) \in \mathcal{O}(\mathcal{Q}(U(a_i, b_i))).
\]
Define \( \psi_i(z) = (G^{\psi_i}f_i)(z) \) \( (i \geq 1) \). By Theorem 1.11-(1) and (2)
\[
L(z, \partial_z)\psi_i(z) = f_i(z) + (G^{\psi_i}f_i)(z),
\]
where \( \psi_i(z) \in \mathcal{O}(U(a_i + \epsilon, b_i - \epsilon)), \quad c = c(\epsilon) \geq 1 \). If \( h < h_1 \), \( h_1 \) being that in Theorem 1.11-(5), \( (G^{\psi_i}f_i)(z) \in \text{Asy}_{\theta_0}(U(a_i + \delta_0, b_i - \delta_0)). \) Put \( w_i(z) = u_i(z) - \psi_i(z) \). Then \( w_i(z) \in \mathcal{O}(U(a_i + \epsilon, b_i - \epsilon)) \) and
\[
L(z, \partial_z)w_i(z) = -(G^{\psi_i}f_i)(z).
\]
Hence if follows from Theorem 6.28 that if \( h \) is small, \( w_i(z) \in \text{Asy}_{\theta_0}(U(a_i + \epsilon, b_i - \epsilon)) \). Now we study \( v_i(z) \). We have
\[
v_i(z) = (G^{\psi_i}f_i)(z) = (G^{\psi_i}f_i)(z) + (G^{\psi_i}f_i)(z)
\]
and
\[
v(z) = \sum_{i=1}^{l} v_i(z) = \sum_{i=1}^{l} (G^{\psi_i}f_i)(z) + \sum_{i=1}^{l} (G^{\psi_i}f_i)(z)
\]
Since \(-\pi/2 < \alpha_0 < \beta_0 < \pi/2 \), it follows from Theorem 1.11-(3) that if \( h < h_0 \), \( (G^{\psi_i}f_i)(z) \in \text{Asy}_{\theta_0}(U(\theta_0 - \delta_0)) \) for all \( i \). By Theorem 1.11-(4), \( f(z) \in \text{Asy}_{\theta_0}(U(\theta_0)) \) implies \( \theta' = \min(\theta_0, \pi) \). So \( v(z) \in \text{Asy}_{\theta_0}(U(\theta_0 - \delta_0)) \) and \( u(z) = v(z) + w(z) \). It follows from Proposition 2.8 that \( u(z) \in \text{Asy}_{\theta_0}(\mathcal{Q}(\theta_0)) \). We can choose \( h, \delta_0, \epsilon \) arbitrary. So \( u(z) \in \text{Asy}_{\theta_0}(\mathcal{Q}(\theta_0)) \). By the rotation of \( z_0 \), we have \( u(z) \in \text{Asy}_{\theta_0}(\mathcal{Q}(\theta_0)) \).
Proof of Theorem 1.7. We may assume $|\theta_0| < \pi/2\kappa$. So let $f(z) \in \mathcal{R} - \text{asy}_i(t_i, \mathcal{O}(\theta_0))$ with $f(z) = g(z) \log z_0 + h(z)$, where $g(z), h(z) \in \text{Asy}_i(t_i, \mathcal{O}(\theta_0))$. By Theorem 1.13 there is a $u(z) \in \mathcal{R} - \text{asy}_i(t_i, \mathcal{O}(\theta_0))$ such that $L(z, \vartheta_i)u(z) - f(z) = \log z_0$ and $\alpha(z) \in \text{Asy}_i(t_i, \mathcal{O}(\theta_0))$ and $(u(z) - u(z)) \in \text{Asy}_i(t_i, \mathcal{O}(\theta_0))$ by Theorem 1.5. So $u(z) \in \mathcal{R} - \text{asy}_i(t_i, \mathcal{O}(\theta_0))$. For general $\theta_0$, we have the assertion by the rotation of $z_0$.

Finally we show Propositions 4.1 and 6.8. In the following we assume $r < R' < R_0 < R, R_1 \leq |t_i| \leq R (i \geq 2), \ |\lambda| \geq A_0$ and try to obtain estimates of holomorphic functions of $\lambda$ and $z$, considering $\tau, t$ to be parameters.

Lemma 7.4. Let $\theta(s) = (R' - s)^{-1}$ and put $s = z_0 + z_1 + \cdots + z_n + ((\lambda - A_0)/(\lambda - A_0))$ \( (|\lambda| \geq 2A_0) \). Then

\[
(7.22) \quad (\lambda_0 - \lambda_0 \theta^{(1)}(s) \left( \sum_{t = 0}^{l} ((|\lambda_0| + |\lambda_0 - A_0|)|t_0|)^{r} / r! \right) \theta^{(t)}(s) \leq A \| \sum_{t = 0}^{l} ((|\lambda_0| + |\lambda_0 - A_0|)|t_0|)^{r} / r! \right) \theta^{(t+1)}(s). \]

Proof. We have

\[
(\lambda_0 - \lambda_0 \theta^{(1)}(s) \left( \sum_{t = 0}^{l} ((|\lambda_0| + |\lambda_0 - A_0|)|t_0|)^{r} / r! \right) \theta^{(t)}(s) \leq A \| \sum_{t = 0}^{l} ((|\lambda_0| + |\lambda_0 - A_0|)|t_0|)^{r} / r! \right) \theta^{(t+1)}(s). \]

where we use $s \theta^{(1)}(s) \leq \theta^{(1)}(s)$. Hence

\[
(\lambda_0 - \lambda_0 \theta^{(1)}(s) \left( \sum_{t = 0}^{l} ((|\lambda_0| + |\lambda_0 - A_0|)|t_0|)^{r} / r! \right) \theta^{(t)}(s) \leq C \| \sum_{t = 0}^{l} ((|\lambda_0| + |\lambda_0 - A_0|)|t_0|)^{r} / r! \right) \theta^{(t+1)}(s) \]

where $\sum_t$ is a finite sum and

\[
(7.23) \quad G^t(z, \lambda, \tau) v_{N}(z, t, \lambda, \tau) \]

\[
+ \sum_{t = 0}^{l} G^t(z, \lambda, \tau) v_{N-e}(z, t, \lambda, \tau) = \delta_{N, n_0} F(x, t, \lambda), \]

where $\sum_t$ is a finite sum and

\[
(7.24) \quad G^t(z, \lambda, \tau) = \lambda^{t-1} (1 - \lambda^{p+1})/\lambda^{t-1}.
\[ G_0(z, \lambda, \tau) = G_0^{-1}(z, \lambda, 0) = \lambda^{p-1} \{ \sum_{k \in \mathbb{N}, 0} \sigma^{(k,1)} a_{k,1}(z) \}, \]

where \( a_{k,1}(z) = a_{k,1}(z, \partial^\tau \partial_\lambda) \) (see Lemma 3.3).

**Proof of Proposition 4.1.** In this case \( \lambda = -1, \ d_{k_p-1} = 0 \) and \( \tau = 0 \). Hence

\[ G_0(z, \lambda) = G_0^{-1}(z, \lambda, 0) = \lambda^{p-1} \{ \sum_{k \in \mathbb{N}, 0} \sigma^{(k,1)} a_{k,0}(z) \}. \]

We show

\[ \lambda^{p-1} v_n(z, t, \lambda) \ll AB^{n+1} \{ \sum_{k=0}^{n+1} \sigma^{(k,1)} a_{k,0}(z) \} \theta^{(n+1)}(s), \]

where \( \theta(s) = (R'-s)^{-1} \) and \( s = z_0 + z_1 + \cdots + z_n + (\lambda - \lambda_0)/(\lambda_0 - \lambda_0) \). We have \( \lambda^{p-1} v_n(z, t, \lambda) \ll A \theta(s) \). Assume (7.27) for \(-1 \leq n \leq N-1\). Since \( a_{k,1}(z) = a_{k,1}(z, \partial^\tau \partial_\lambda) \) is an operator with the order \( \leq s+r \), from Lemma 7.2,

\[ \lambda^{p-1} a_{k,1}(z, \partial^\tau \partial_\lambda) v_{N-q}(z, t, \lambda) \ll AB^{N-q+1} \{ \sum_{k=0}^{N-q+1} \sigma^{(k,1)} a_{k,0}(z) \} \theta^{(N-q+s+r+1)}(s). \]

It follows from Lemma 3.4, (3.15) and Lemma 7.4 that

\[ Q_{k+1}^\tau r, \sigma (n + s + r, \lambda t_0 - \lambda \partial \lambda) \]

\[ \times \{ \sum_{k=0}^{N-q+1} \sigma^{(k,1)} a_{k,0}(z) \} \theta^{(N-q+s+r+1)}(s) \]

\[ \ll A \{ \sum_{k=0}^{N-q+s+r+1} \sigma^{(k,1)} a_{k,0}(z) \} \theta^{(N-q+s+r+1)}(s). \]

So

\[ \lambda^{p-1} G_0^{-1}(z, \partial, \lambda, \tau) v_{N-q}(z, t, \lambda) \ll AB^{N} \{ \sum_{k=0}^{N-q} \sigma^{(k,1)} a_{k,0}(z) \} \theta^{(N+1)}(s). \]

Since \( \lambda^{p-1} G_0^{-1}(z, \lambda, 0)^{-1} \ll A(R'-s)^{-1} \), we have (7.27) for \( n = N \). Thus

\[ \lambda^{p-1} v_n(z, t, \lambda) \ll AB^{n+1} \{ \sum_{k=0}^{n+1} \sigma^{(k,1)} a_{k,0}(z) \} \theta^{(N+1)}(s) \]

for a small neighborhood of \( z = 0 \).

We proceed to the proof of Proposition 6.8. In this case \( i = 1 \) and
From Proposition 6.4 we have

Lemma 7.5. It holds that in $\tau(i)$ ($0 \leq i \leq p-1$)

\begin{equation}
|\lambda^{m-(1-\alpha_1)d_m}G_0(z, \lambda, \tau)^{-1}| \leq A |\lambda|^{\beta_{k_i-1}+1} |\tau|^d k_{i-1}.
\end{equation}

Lemma 7.6. There exists a constant $A$ such that for $\tau \in \tau(i)$

\begin{equation}
\left| \frac{\lambda^{m-(1-\alpha_1)d_m}G_0(z, \lambda, \tau)^{-1}}{G_0(z, \lambda, \tau)} \right| \leq A.
\end{equation}

Proof. We have on $\{ |\tau| = b_{i-1} \mid \lambda^{\alpha_i-1} \}$

\begin{equation}
|\lambda^{-(1-\alpha_1)\tau+\beta_{k_i}+1}| \leq C |\lambda|^{-(1-\alpha_1)\tau-\beta_{k_i-1}} \leq C |\lambda|^{-(1-\alpha_1)\tau+\beta_{k_i-1}}.
\end{equation}

Since

\begin{equation}
(1-\alpha_1)\tau+\beta_{k_i},(r+d_k,i)(\alpha_1-\alpha_{i-1})
\end{equation}

\begin{equation}
=(1-\alpha_{i-1})\tau+(\alpha_1-\alpha_{i-1})d_k,i+\beta_{k_i,i} \geq \beta_{k_i-1} + (\alpha_1-\alpha_{i-1})d_{k_{i-1}},
\end{equation}

we have

\begin{equation}
|\lambda^{-(1-\alpha_1)\tau-\beta_{k_i}+1}| \leq C |\lambda|^{-\beta_{k_i-1}} |\tau|^d k_{i-1}.
\end{equation}

On the other hand we have

\begin{equation}
(1-\alpha_1)\tau+(\alpha_1-\alpha_{i})d_k,i+\beta_{k_i,i} \geq (\alpha_1-\alpha_{i})d_k,i+\beta_{k_i-1}+(\alpha_1-\alpha_{i})d_{k_{i-1}},
\end{equation}

Hence we have

\begin{equation}
|\lambda^{-(1-\alpha_1)\tau-\beta_{k_i}+1}| \leq C |\lambda|^{-\beta_{k_i-1}} |\tau|^d k_{i-1}
\end{equation}

on

\begin{equation}
\{ |\tau| = b_i |\lambda|^{\alpha_i-1} \} \cup \{ \lambda^{\alpha_i-1} \partial K_i(\eta) \}.
\end{equation}

It follows from Lemma 7.5 that (7.31) holds on the boundary of $\tau(i)$. By the maximal principle of holomorphic functions implies (7.31) holds on $\tau(i)$.

Proof of Proposition 6.8. We show

\begin{equation}
\lambda^{m-(1-\alpha_1)d_m}(\tau-\tau_1)^m \omega_k(z, t, \lambda, \tau)
\end{equation}

\begin{equation}
\ll A \left( \frac{B}{|\tau|} \right)^{n+1} \{ \sum \theta^s \theta^t (\lambda_\alpha |\lambda_\alpha - A_\lambda | |t_\alpha|) \} \theta^{(n+1)}(s), \quad h \neq m,
\end{equation}

where $\theta(s) = (R-s)^{-1}$ and $s = z_0 + z_1 + \cdots + (\lambda - \lambda_0) / (\lambda_0 - A_\lambda)$. (7.32) is true for $n = -1$. Assume (7.32) for $\tau \in \tau(i)$ and $-1 \leq n \leq N-1$. Since $a_{k,i}(z, \partial \partial^*)$ is an operator with the order $s+r$, from Lemma 7.3,
(7.33) \( \lambda^{m-(1-a)} \delta^{\tau} a_{\tau} \partial_{\tau}^r w_{N-r}(z, t, \lambda, \tau) \leq A \left( \frac{B}{|\tau|} \right)^{n-q+1} \{ \sum_{k=0}^{n} \delta^s |(\lambda_0^0 + |\lambda_0 - A_0|)| t_0^i / i \} \theta^{(N-q+s+r+1)}(s). \)

By the same method as the proof of Proposition 4.1, we have

(7.34) \( \lambda^{m-(1-a)} \delta^{\tau} a_{\tau} (n+s+r, \lambda t_0 - \lambda \partial_1) a_{\tau} \partial_0^r w_{N-r}(z, t, \lambda, \tau) \leq A \left( \frac{B}{|\tau|} \right)^{n-q+1} \{ \sum_{k=0}^{n} \delta^s |(\lambda_0^0 + |\lambda_0 - A_0|)| t_0^i / i \} \theta^{(N-q+s+r+1)}(s). \)

Thus by Lemma 7.6 we have (7.32) for \( n=N. \) Since \( \theta^{(n)}(s) = n!/(R^r - s)^{n+1}, \) we have (6.41). By the same method, we can show

(7.35) \( \lambda^{m-(1-a)} \delta^{\tau} w_{N}(z, t, \lambda, \tau) \leq A \left( \frac{B}{|\tau|} \right)^{n+1} \{ \sum_{k=0}^{n} \delta^s |(\lambda_0^0 + |\lambda_0 - A_0|)| t_0^i / i \} \theta^{(n+1)}(s) \)

and we have (6.42).
