Abstract
Carbon Fiber Reinforced Thermoplastics (CFRTP) have attracted attention in the automotive industry for their productivity and high specific strength and modulus. To guarantee the durability of CFRTP, it is important to understand the mechanical properties of CFRTP under practical service temperature. Since the mechanical properties of CFRTP are affected not only by reinforcement fibers and matrix resins but also by the fiber matrix interface, to reveal the fiber/matrix interface properties is one of the important issues to be solved. Among thermoplastic resins, polyamide (PA) is expected to be used for the matrix of CFRTP, owing to good interfacial adhesion to the carbon fiber, and good moldability. Although tensile tests of CFRTP under the high temperature environment were performed, the effects of temperature on the fiber/matrix interfacial shear strength have not been fully clarified. In this study, in order to evaluate the fiber/matrix interfacial properties at 25 °C, 40 °C and 80 °C, single fiber pull-out tests, measurement of the thermal expansion coefficient of the resin, and analysis of the thermal expansion of the resin were performed. As temperature rose, resin expanded and interfacial shear strength of the CF/PA model composites decreased. This result suggests that the decrease of the interfacial shear strength by temperature rise is caused by the expansion of the resin.

Key words: Fiber/matrix interfacial shear strength, Polyamide, Carbon fiber, Pull-out test, High temperature

1. Introduction

In order to obtain good gasoline mileage in mass-produced automobiles, to reduce the weight of a car body by using Carbon Fiber Reinforced Thermoplastics (CFRTP) has attracted attention as thermoplastics are excellent in productivity and recyclability. (Asmatule et al., 2013) (Matsutsuka et al., 2005) Among thermoplastic resins, polyamide (PA) is expected to be used for the matrix of CFRTP, owing to good interfacial adhesion to the carbon fiber, and good moldability. (Beckwith, 2008) To apply CFRTP to automobiles, it is important to understand the mechanical properties of CFRTP under practical service temperature. For example, the roof components, which have the highest temperature among vehicle structural components, rise up to 83.5 °C under the scorching sun. (JIS D 0204, 1967) Since the mechanical properties of CFRTP are affected not only by reinforcement fibers and matrix resins but also by the fiber matrix interface, it is necessary to consider the effects of temperature on the fiber/matrix interfacial properties of CFRTP. (Sethi and Ray, 2015) Vieille et al reported that the tensile strength of CF/PPS under a high temperature environment was smaller than that of a room temperature one, and by SEM observation of fracture surfaces, the degradation of fiber/matrix interfacial properties was considered to be the reason for this. (Vieille and Taleb, 2011) However, the effects of temperature on the fiber/matrix interfacial properties have not been evaluated. Although a large quantity of data on the fiber/matrix interfacial properties of composites can be obtained in carbon fiber reinforced...
thermoset composites (CFRP), data on the fiber/matrix interfacial properties of CFRTP is not sufficiently available compared with CFRP. (Kim and Mai, 1998) (Koyanagi et al., 2010) (Koyanagi et al., 2011) (Sethi and Ray, 2015) (Tanaka et al., 2002) (Tanaka et al., 2003) In this study, in order to evaluate the fiber/matrix interfacial properties at 25 °C, 40 °C and 80 °C, single fiber pull-out tests, measurement of the thermal expansion coefficient of the resin, and analysis of the thermal expansion of the resin were performed, and the degradation mechanism of the fiber/matrix interfacial properties at high temperature was discussed.

2. Materials and Experimental procedure

2.1 Materials

PAN-based carbon fibers were used for the single fiber pull-out tests. Polyamide 6 (PA6: 1013B, Ube Industries, Ltd., Japan) and Polyamide 12 (PA12: 3014U, Ube Industries, Ltd., Japan) were used for the matrix.

2.2 Single fiber pull-out test

Figure 1 shows the shape and dimension of a pull-out specimen. After a single carbon fiber was glued to a tab, it was attached to a micromanipulator. PA resin was placed on the aluminum plate heated to 250 °C for PA6 and 220 °C for PA12.

After the single fiber was embedded into the melted resin by operating the micromanipulator, it was air-cooled. These specimens are referred to as CF/PA model composites, and these CF/PA model composites were used for single fiber pull-out tests. After chucking the tab of a pull-out specimen, the supporting part of the tab was cut and a pull-out test was performed using a testing machine for micro material (MMT-11 N, Shimadzu Co., Japan, Load capacity: 10 N) with a constant displacement rate of 1.67×10⁻⁶ m/s. The temperature condition at room temperature was 25 °C and the single fiber pull-out tests under the high temperatures of 40 °C and 80 °C were conducted on the hot plates as shown in Fig. 2. Figure 3 shows a schematic drawing of an embedded fiber and Figure 4 shows a pulled-out fiber observed by scanning electron microscope (SEM, JSM-6390LT, JEOL Ltd., Japan). The precise embedded fiber length and fiber diameter were measured by using SEM after the pull-out tests. The fiber/matrix interfacial shear strength, \( \tau \), was calculated by the following Eq. (1):

\[
\tau = \frac{F_{\text{max}}}{\pi dl}
\]

where \( F_{\text{max}} \) is the maximum load in the pull-out test, \( d \) is the fiber diameter and \( l \) is the embedded fiber length.

![Fig. 1  Shape and dimension of a pull-out specimen.](image-url)
2.3 Measurement of thermal expansion coefficient of resins

The thermal expansion coefficients of PA6 and PA12 were measured by a thermomechanical analyzer (TMA-60, Shimadzu Co., Japan). The testing load was 2 g, the rate of temperature rise was 3 °C/min, and the temperature conditions for the resins were from 30 °C to 140 °C. The thermal expansion coefficient was calculated using the following Eq. (2):

\[ \Delta L = L \alpha \Delta T \]  

where \( \Delta L \) is the displacement, \( L \) is the original length, \( \alpha \) is the thermal expansion coefficient and \( \Delta T \) is the difference of temperature.
2.4 Analysis of the thermal expansion

FEM analysis to estimate the thermal expansion of the resins as temperature rose was conducted using the commercial FEM software COMSOL Multiphysics 4.4. The analysis was performed using coupled analysis including a structural mechanics module and heat transfer module. Figure 5 shows the analyzed model of the resin. The hemispherical resin made of polyamide, whose size is 3 mm in diameter and 1.5 mm in depth, has a cylindrical hole. The size of the hole is 7 µm in diameter and 50 µm in length, in which a carbon fiber is embedded. The total number of tetrahedral elements was 119,178. The initial temperature of the resin was set to 25 °C. The boundary conditions were selected as shown in Fig. 6. The bottom surface was set to 40 °C and 80 °C. To consider the heat transfer to the air, the air contact surface was set as the heat transfer condition. The constraint conditions were selected as shown in Fig. 7. For the constraint conditions of the bottom surface, only the displacement of the x direction was set to zero. The center of the bottom surface was fixed. The material properties used in this analysis are shown in Table 1. The thermal conductivity ($\lambda$), Young’s modulus ($E$) and Poisson’s ratio ($\nu$) of the dried resins of PA6 and PA12 at room temperature were provided by Ube Industries, Ltd.

3. Results and discussion

3.1 Thermal expansion coefficient of resins

Figure 8 shows the relationship between time and temperature, and displacement of PA6 and PA12. Figure 9 shows the calculated coefficients of the thermal expansion of PA6 and PA12. These results show that the thermal expansion coefficients of both resins increased as temperature rose, and that of PA12 was higher than that of PA6 regardless of the measured temperature.

3.2 Single fiber pull-out test

Figure 10 shows the fiber/matrix interfacial shear strengths of CF/PA6 and CF/PA12 obtained by the single fiber pull-out tests. The fiber/matrix interfacial shear strengths of CF/PA6 model composites at 25 °C, 40 °C and 80 °C were 43.2 MPa, 34.9 MPa and 24.4 MPa, respectively. On the other hand, those of CF/PA12 model composites at 25 °C, 40 °C and 80 °C were 30.3 MPa, 23.2 MPa and 20.4 MPa, respectively. The results show that the fiber/matrix interfacial shear strengths of CF/PA6 model composites were decreased by 20 % at 40 °C and 44 % at 80 °C. And those of CF/PA12 model composites were decreased by 24 % at 40 °C and 33 % at 80 °C. The interfacial shear strengths of both specimens decreased as temperature rose.

3.3 Analysis of the thermal expansion of resin

Figure 11 shows displacement distributions of the analyzed resin model. Figure 12 shows the enlarged views of the holes of PA6 and PA12 at 40 °C and 80 °C. The solid lines are outlines at 25 °C and the dotted lines are those at heated temperature. Figure 13 shows the hole diameter of both resins at each temperature. The hole diameter of PA6 was increased by 0.26% at 40 °C and 0.79% at 80 °C compared with that at 25 °C. And the hole diameter of PA12 was increased by 0.31% at 40 °C and 0.92% at 80 °C compared with that at 25 °C. These results show that the hole diameter of both resins increased as temperature rose. Figure 14 shows the relationship between interfacial shear strength and hole diameter. The interfacial shear strengths of both specimens decreased as hole diameter rose. Wang et al reported that the residual thermal stress in the radial direction, which is formed during cooling of the micro-droplet from melting to ambient temperature, affects the interfacial shear strength of a CF/PPS composite evaluated by micro bond test (Wang et al., 2015). These results show that the interfacial shear strength decreases by temperature rise due to the reduction of the residual thermal stress in the radial direction caused by thermal expansion of the hole of the resin in the radial direction.

4. Conclusion

To investigate the effects of temperature on the fiber/matrix interfacial properties of CF/PA6 and CF/PA12 model composites, single fiber pull-out tests at 25 °C, 40 °C and 80 °C, measurement of the thermal expansion coefficient of the resin, and analysis of the thermal expansion of the resin were conducted. The investigation yielded the following conclusions:

1. Interfacial shear strengths of both CF/PA6 and CF/PA12 model composites decreased as temperature rose.
2. The thermal expansion coefficients of both resins increased as temperature rose and that of PA12 was higher than that of PA6 regardless of the measured temperature.
3. From FEM analysis of the hole diameter of resins at high temperature, hole diameters of both resins increased as temperature rose. These results suggest that the interfacial shear strength decreases by temperature rise due to the reduction of the residual thermal stress in the radial direction caused by thermal expansion of the hole of the resin in the radial direction.
