The Reexpansion of Brain after Surgery by 5 cm Skull Trephine in Case of Chronic Subdural Hematoma

Yuji Miyazaki and Norio Mikami

Department of Neurosurgery, Sapporo Medical College and Hospital

The postoperative reexpansion of brain after surgery by 5 cm skull trephine in cases of chronic subdural hematomas reported based on the experiences of 43 cases.

The course of reexpansion of brain postoperatively is divided into 3 groups by X-ray observation of location of clip which placed on the cortical surface.

Group I is rapidly reexpansion in short period progressively.

Group II is that reexpansion is gradually and has fluctuated period during this period.

Group III is that the distance between clip and inner surface increased in course of reexpansion followed gradual reexpansion.

In proportion to an increase of traffic, and industrial accident, quite a few patients are complaining of such indefinite symptoms as headache, heavy feeling, nausea, vomiting, vertigo, tinnitus, and numbness of arms without neurological abnormalities after head- or neck trauma. Greater difficulties would be encountered in treatment and diagnosis of posttraumatic cerebral syndrome under a situation mentioned above. A spinal tap was performed for eighty-three
