12. Follow-up Study of the Operative Treatment on the Spinal Cord Tumor and the Chronic Adhesive Arachnoiditis

S. ARAKI*, N. TSUYAMA, M. NAGANO, I. ABE*, K. YAMAGATA** AND R. SUZUKI***

Sixty-two cases of spinal cord tumor and thirty-nine cases of chronic adhesive arachnoiditis, diagnosed on our operative findings in the past ten years, are reported with statistical considerations. These tumors include thirty-six neurinomas, seven dermoids, five astrocytomas, four meningiomas, four hemangiomas, one glioma, ependymoma, psamoma, neurofibromatosis, cholesteatoma and myxoma. Their myelograms are again compared with the operative findings.

The daily activities as well as physical findings are our main criterion to estimate the long-term results, the longest being twelve years after operation. It revealed that about a third of the patients had returned to their preoperative occupations without any discomfort, while a few had died in the post-operative period and about a half of them, most of whom were with chronic arachnoiditis, were disabled.

13. Experimental Histological Studies on the Spinal Injuries

Kiichi SUZUKI, Osamu NATSUME, AND Atsuo SUGITA
Urological Clinic, Tohoku University School of Medicine

The section of the ventral or dorsal horn and the half-side section of the spinal cord in the level of lumbar or sacral segment, which is assumed to be related to the vesical function, was performed on 20 adult dogs to clarify the various functions of the urinary bladder. Thence, the site of lesion and the degeneration of nerve fibers in the spinal cord were examined according to the Marchi's staining for continuous specimens, and furthermore, degeneration in the peripheral nerves was observed.

With the obtained results, the ascending site of the degeneration in the dorsal tract following the spinal lesion was confirmed. In the peripheral nerve with the left half-side section of the lumbar segment, degeneration in the L2-L4 ventral roots, in the inferior splanchnic nerve, in the hypogastric nerve were found, respectively (Table 1). It is also noted that almost or all the small- and medium-sized fibers originated from the ventral roots joined into the inferior splanchnic nerves. In the case with half-side section of sacral segment, much
degeneration of fibers in the $S_2$-$S_3$ ventral roots, and little in the $S_1$-$S_3$ dorsal roots was observed. Furthermore, degenerated fibers in the pelvic nerve, and the vesical nerve were found significantly. These were small- and medium-sized fibers, respectively (Table 2). The results following the one-side section of the

anterior horn of the spinal cord were almostly similar to those of the proceedings.

With these experiments, it was clarified that many degenerated fibers in the peripheral nerves were recognized following spinal injuries, and these fibers mainly originated in ventral roots. It was also noted that degeneration of small-sized fibers in ventral roots so as to the dorsal roots was to be related with the symptoms of autonomic nerves recognized after the spinal injuries.

14. Pathophysiological Studies on the Anastomosis of the Nerve The 1st Report

Hiroaki Kawakita, Kazuo Nishimura, Norikazu Sawa, Kiyoshi Uematsu, Syoji Bando, Tuyoshi Fujimoto, Ken Ito and Hiro Toyohara

The Fujita's Surgical Clinic, Kobe Medical College

Studies on the anastomosis of the nerves were made by methods using the action potential tracing of nerves and the phase microscopic observation in dogs.

The results obtained were as follows:

1. In regard to the difference of regeneratic ability between the thickness of the nerve fibers and the kind of neurons.
