Abstract: Numerous pieces of evidence have revealed that oxaliplatin (OXA) evokes mechanical and cold hypersensitivity. However, the mechanism underlying these bothersome side effects needs to be further investigated. It is well known that cyclooxygenase-2 (COX-2) and extracellular signal-regulated kinases (ERK1/2) signaling play crucial roles in several pain states. Our previous data showed that Akt2 in the dorsal root ganglion (DRG) participated in the regulation of OXA-induced neuropathic pain. But it is still unclear whether spinal ERK1/2 signaling is involved in the regulation of OXA-induced hyperalgesia, and the linkage between COX-2 and ERK1/2 signaling in mediating OXA-induced hyperalgesia also remains unclear. In this research, we investigated the possible mechanism of celecoxib, a COX-2 inhibitor, in OXA-induced neuropathic pain. Our results show that single dose of OXA (12 mg/kg) significantly attenuated both the tail withdrawal latency (TWL) and mechanical withdrawal threshold (MWT) at days 4 after the OXA treatment. Administration of celecoxib (30 mg/kg/day) for 4 and 6 days inhibited the decrease in TWL and MWT, and each was significantly higher than that of the OXA+vehicle group and was equivalent to that of the vehicles group. OXA increased the expression of cyclooxygenase-2 (COX-2) mRNA and phosphorylated extracellular signal-regulated kinases 1/2 (pERK1/2) protein in the lumbar 4-5 (L4-5) spinal cord dorsal horn neurons. Administration of celecoxib for 7 days suppressed the increase in expression of COX-2 and pERK1/2 induced by OXA. Our findings suggested that COX-2 and ERK1/2 signaling in spinal cord contributed to the OXA-induced neuropathic pain. (DOI: 10.1293/tox.2016-0032; J Toxicol Pathol 2016; 29: 253–259)

Key words: oxaliplatin, cyclooxygenase-2, pERK1/2, neuropathic pain, celecoxib

Introduction

Oxaliplatin (OXA), a third-generation platinum-based chemotherapy agent, is considered a central component in the treatment of advanced colorectal cancer. OXA treatment has prolonged the lives of many people diagnosed in advanced stages of the colorectal cancer. Despite its efficacy, there are numerous adverse effects associated with OXA. Neurotoxicity is a common adverse effect of oxaliplatin that usually presents as peripheral neuropathy. The development of a neuropathic syndrome impairs quality of life and potentially results in chemotherapy dose reductions and/or early discontinuation. There are 2 forms of OXA-induced neurotoxicity: acute neuropathy and chronic neuropathy. The acute form occurs in >90% of patients and may begin during the infusion or within hours of completion. Chronic neuropathy is cumulative and is most commonly seen in patients who have received doses of 540 mg/m² or more.

Accumulating studies have reported the important role of OXA in inducing cold and mechanical allodynia. Many studies have focused on the side effects of OXA in the dorsal root ganglion (DRG), which contains the cell bodies of the primary sensory neurons responsible for transduction and modulation of sensory information and transmission of it to the spinal cord. OXA-induced mechanical allodynia is associated with spinal NMDA receptor subunit NR2B upregulation, while selective NR2B antagonists Ro25-6981 and ifenprodil attenuate the OXA-induced pain behaviors. Milnacipran, a serotonin–noradrenaline reuptake inhibitor,
Celecoxib Alleviates Oxaliplatin-induced Neuropathic Pain

is effective against OXA-induced mechanical allodynia, and the anti-allodynic effect is mainly mediated by actions on the spinal cord. Moreover, bee venom acupuncture treatment alleviates OXA-induced acute cold allodynia in rats via activation of the serotonergic system, especially spinal 5-HT₃ receptors.

It is well known that cyclooxygenase-2 (COX-2) and extracellular signal-regulated kinases (ERK1/2) signaling play crucial roles in several pain states. In the present study, we explored the expression levels of COX-2 and ERK1/2 in L4-5 segments of the spinal cord, from which the hind limb receives innervations, of OXA-treated mice. The roles of the COX-2 inhibitor celecoxib in OXA-induced pain behaviors and its underlying mechanisms were also investigated. It is hoped that our novel understanding of OXA-induced neurotoxicity in cancer therapy will provide a new therapeutic strategy to prevent hyperalgesia.

Materials and Methods

Animals

Adult Male C57BL/6J mice (10 weeks old; 49–51 passages from the original colony) were provided by the Center of Laboratory Animal Science of Nanchang University. The mice were fed a standard laboratory diet under controlled temperature and a 12-h light/dark cycle at 20–22°C. All experimental procedures were approved by the Institutional Animal Care and Use Committee of the Medical College of Nanchang University and were performed in accordance with the principles outlined in the National Institutes of Health Guide for the Care and Use of Laboratory Animals.

Experimental protocols

Mice were randomly divided into 3 groups, with 10 mice in each group: a vehicles group, an OXA+vehicle group, and an OXA+celecoxib (30 mg/kg/day) group. In the OXA+vehicle group and the OXA+celecoxib group, the mice were injected intraperitoneally with single doses of 12 mg/kg body weight of OXA (Qilu Pharmaceutical Co., Ltd, Jinan, China) dissolved in 5% glucose solution on day 0 (d0). Celecoxib was dissolved in 0.5% methylcellulose vehicle (Sigma-Aldrich, St Louis, MO, USA) and was delivered twice daily by oral gavage for 7 days, beginning on d1. The same volume of 5% glucose solution was intraperitoneally injected in the vehicle group. The mice in the vehicles and the OXA+vehicle groups were delivered the same volume of 0.5% methylcellulose according to the procedure for the OXA+celecoxib group. The dosage of celecoxib (30 mg/kg/day) was chosen according to a previous report. This dose of celecoxib was an effective level against the neuropathic pain-induced by OXA. The pain behaviors were tested once every 2 days from d0 before OXA administration to d8. They were tested every day beginning 24 h after first dose of celecoxib.

OXA treatment is a well characterized model used for studying neuropathic pain. Based on the OXA concentration used, there are generally two ways to induce hyperalgesia: long-term treatment with a low dose of OXA and short-term treatment with high dose of OXA. In this study, the dosage of OXA was chosen according to a previous report. A single dose of a high concentration of OXA was used to induce hyperalgesia. In brief, single doses of 12 mg/kg body weight of OXA were injected intraperitoneally. At d8, all the mice were deeply anesthetized with pentobarbital sodium (100 mg/kg sodium pentobarbital, i.p.) and sacrificed by decapitation.

Cold-sensitivity detection

The behavioral signs of cold allodynia were measured by a tail immersion test in cold water. Each mouse was lightly immobilized in a plastic holder, and its tail was dipped in cold water. The tail was immersed in 4°C water, and then the tail withdrawal latency (TWL) was counted. The tail immersion test was repeated 3 times at 5 min intervals. The average latency was taken as a measure for the severity of cold allodynia. All behavioral tests were performed blind.

Mechanical-sensitivity detection

Mechanical allodynia measurement was carried out as previously described. In brief, the mechanical withdrawal threshold (MWT) was determined to evaluate mechanical hyperalgesia using calibrated von Frey filaments (BME-403, Institute of Biomedical Engineering, Tianjin, China). The measurement was repeated 3 times at 30 s intervals. The average was taken as the mechanical withdrawal threshold. All behavioral tests were performed blind.

Real-time PCR quantification

The whole spinal cord was collected by pressure expulsion with ice cold saline. The dorsal and ventral parts of the L4-5 spinal cord were dissected on an ice cooled glass dish. Total RNA from L4-5 spinal cord dorsal segments was isolated using TRIzol (Invitrogen, Carlsbad, CA, USA) according to the manufacturer’s protocol. Reverse transcription was performed using 1,000 ng total RNA as a template and a Applied Biosystems Reverse Transcription Kit (Applied Biosystems, Foster City, CA, USA). Real-time quantitative PCR for COX-2 was performed using an ABI 7500 Real-Time PCR System (Applied Biosystems, Foster City, CA, USA). The expression level of COX-2 was normalized to GAPDH. The probe was purchased from Applied Biosystems. All assays were performed in triplicate. The average fold change relative to the vehicles group was calculated in each group.

Immunohistochemistry

Spinal cord segments of L4-5 were analyzed from 6 mice in each group. The formalin-fixed, paraffin-embedded tissues were cut, and sections (5 μm thick) were used for immunohistochemistry (IHC) detection. Six nonadjacent sections from each specimen of the L4-5 spinal cord were selected. IHC was carried out as previously described, using primary antibodies against pERK1/2 (1:100; Santa Cruz Biotechnology, Dallas, TX, USA). A rabbit kit (PV-6001, Institute of Biomedical Engineering, Tianjin, China) was used to induce hyperalgesia.
ZSGB-BIO, Beijing, China) was used as a secondary antibody according to the manufacture’s instructions. Protein localization was detected following incubation with diaminobenzidine and \( \text{H}_2\text{O}_2 \) for 2 min. Finally, sections were dehydrated in graded alcohols and mounted with neutral balsam. The numbers of pERK1/2-positive neurons from one side of spinal cord dorsal horn of each mouse were counted. Data from 6 sections of the same mouse were averaged.

**Western blot**

L4-5 spinal cord dorsal segments were homogenized in radioimmunoprecipitation assay (RIPA) buffer. Samples of 30 µg of total protein were separated by 10% SDS-polyacrylamide gel electrophoresis and transferred onto a polyvinylidene difluoride membrane. After incubation with primary antibody pERK1/2 (1:1,000; Santa Cruz Biotechnology, Dallas, TX, USA) or total extracellular signal-regulated kinase1/2 (tERK,1:1,000; Cell Signaling Technology, Danvers, MA, USA), the membrane was incubated with peroxidase conjugated secondary antibodies (Cell Signaling Technology, Danvers, MA, USA). Immunodetection was completed using Pierce-enhanced chemiluminescence substrate (Thermo Scientific, Waltham, MA, USA), and the membrane was then exposed to X-ray film. The average fold change relative to the vehicles group was calculated in each group.

**Statistical analysis**

Data are shown as the mean ± SD. Comparisons of means between two groups were carried out using a t-test. Statistical comparisons were performed by analysis of variance (ANOVA) with Dunnett’s test for multiple comparisons. A value of \( P<0.05 \) was considered to be significant.

**Results**

**Celecoxib attenuated the cold and mechanical hypersensitivity induced by OXA**

The TWL and MWT were measured to evaluate the effects of celecoxib on pain behaviors of OXA-treated mice. The results showed that both the TWL and MWT thresholds significantly decreased in the OXA+vehicle group (8.50 s and 6.83 g, respectively) when compared with the vehicles group (11.22 s and 8.46 g, respectively) at d4 and remained at low levels. At d8, the TWL and MWT thresholds (6.97 s and 5.93 g, respectively) were still lower when compared with those of the vehicles group (Fig. 1). Celecoxib significantly increased the TWL threshold (from 8.50 s to 9.95 s) beginning at d4. At d6, the TWL threshold continued to increase. Celecoxib significantly upregulated the MWT threshold (from 6.07 g to 7.45 g) beginning at d6. At d8, both the TWL and MWT thresholds still were upregulated by celecoxib (Fig. 1). The results suggested that celecoxib alleviated the OXA-induced pain behaviors.

**Celecoxib decreased pERK1/2-positive neurons in the L4-5 spinal cord dorsal horn**

The immunoreactivity of pERK1/2 was detected using immunohistochemistry. The results showed that OXA increased the number of pERK1/2-positive neurons from 8.67 to 30.67 neurons and that administration of celecoxib efficiently decreased the number of pERK1/2-positive neurons from 30.67 to 15.17 neurons (Fig. 2). The results imply that ERK1/2 signaling may be involved in the regulation of OXA-induced hypersensitivity.

**Celecoxib suppressed the OXA-induced COX-2 mRNA expression**

COX-2 mRNA was detected by real-time PCR. COX-2 mRNA expression was significantly upregulated (2.10 folds) in the OXA+vehicle group as compared with the vehicles group. Administration of celecoxib significantly suppressed the expression of COX-2 mRNA compared with the OXA+vehicle group (Fig. 3).

**Celecoxib downregulated the level of OXA-induced pERK1/2 protein**

To investigate the potential mechanism of celecoxib in reversing of OXA-induced hyperalgesia in term of protein level, the pERK1/2 protein was measured by Western blot. The level pERK1/2 protein significantly increased to 261% in the OXA+vehicle group as compared with the vehicles group.
Fig. 2. Celecoxib decreased pERK1/2-positive neurons in the L4-5 spinal cord dorsal horn of OXA-treated mice. (A–C) pERK1/2 immunoreactivities (brown) were detected. Arrowheads indicate representative pERK1/2-positive neurons. Scale bar is 40 µm. (D) The numbers of pERK1/2-positive neurons on one side of the L4-5 spinal cord dorsal horn. Data are shown as the mean ± SD (n = 6). **P<0.01; ***P<0.001 (both vs the vehicles group). ##P<0.01 (vs the OXA+vehicle group).

Fig. 3. OXA increased the COX-2 mRNA in L4-5 spinal cord dorsal horn. COX-2 mRNA was detected by real-time PCR. Data are shown as the mean ± SD (n = 6). **P<0.01; ***P<0.001 (both vs the vehicles group). ##P<0.01 (vs the OXA+vehicle group).

Fig. 4. Celecoxib decreased the expression of pERK1/2 protein in the L4-5 spinal cord dorsal horn of OXA-treated mice. pERK1/2 protein was measured by Western blot. Data are shown as the mean ± SD (n = 4). *P<0.05; **P<0.01 (both vs the vehicles group). #P<0.05 (vs the OXA+vehicle group).
group. Administration of celecoxib significantly decreased pERK1/2 protein expression (Fig. 4). These data further illustrated that the spinal COX-2 and pERK1/2 pathway mediated OXA-induced hypersensitivity.

Discussion

The present study demonstrated the following novel findings: (1) Administration of oxaliplatin (OXA) increased spinal cyclooxygenase-2 (COX-2) mRNA and ERK1/2 protein. (2) Celecoxib suppressed the COX-2 and ERK1/2 pathway in the spinal cord of OXA-treated mice. (3) Celecoxib alleviated OXA-induced hyperalgesia through inhibition of spinal pERK1/2 protein. These results reveal a critical role of spinal COX-2 and ERK1/2 signaling in OXA-induced neuropathic pain.

Neuropathic pain, arising from lesions to peripheral nerves, is present in many neurological diseases and occurs in patients with diabetes, cancer, and AIDS. Moreover, it is frequently induced by chemotherapy. It is caused by an injury to the peripheral or central nervous system. Characteristic features of neuropathic pain are hyperalgesia, allodynia, and spontaneous pain. Numerous pieces of evidence have shown that upregulation of spinal pain mediators and related receptors contributes to neuropathic pain.

Nonsteroidal anti-inflammatory drugs (NSAIDs) are strong cyclooxygenase (COX) inhibitors that are widely used in the management of acute and inflammatory pain. Two isoforms of COX, COX-1 and COX-2, are targets of NSAIDs. A variety of studies have shown that COX-2 inhibitors play a pivotal role in neuropathic pain. Ibuprofen attenuates hyperalgesia following chronic constriction injury by suppressing the expression of P2X3 receptors in the DRG. Celecoxib produces an antihyperalgesic and antiallodynic effect in diabetic rats. Furthermore, spinal COX-2 contributes to neuropathic pain. Spinal nerve ligation causes mechanical allodynia, which is accompanied by increased expression of spinal COX-2 immunoreactivity. Intrathecal administrations of the COX-2 inhibitors attenuate streptozotocin-induced mechanical hyperalgesia through inhibition of spinal COX-2 protein. It has been revealed that the COX-2 inhibitor celecoxib can inhibit tumor growth and enhance the anti-tumor effect of OXA through their synergistic role in inhibiting different targets.

However, the effects of spinal COX-2 on OXA-induced neuropathic pain are poorly understood. In the present investigation, we found that administration of celecoxib could alleviate both mechanical and cold hypersensitivity induced by OXA through inhibition of spinal COX-2 mRNA. Our findings may provide a clinically useful evidence for the dual roles of celecoxib in cancer therapy: enhancing the anti-tumor effect of OXA and alleviating OXA-induced hyperalgesia.

Chemotherapy-induced peripheral neuropathy could trigger the pathophysiological changes in the spinal cord, as evidenced by neuroinflammatory processes including the release of pro-inflammatory cytokines. OXA increases production of pro-inflammatory and neuroexcitatory cytokines (TNF, IL-1β) in the dorsal horn of the spinal cord. COX-2, an inflammatory mediator, increases in the spinal cord dorsal horn neurons following L5 spinal nerve ligation. Our previous data show that OXA can increase the expression of COX-2 in the DRG. In the present study, we also found that OXA increased the COX-2 mRNA expression in the spinal dorsal horn. However, administration of 2.4 mg/kg OXA for 5 consecutive days every week for 3 weeks slightly increased the expression of COX-2 protein, with no significant difference in the rat spinal cord. Therefore, OXA increased the spinal COX-2 level in a dose-dependent manner. The mechanisms of the OXA-induced increase in COX-2 mRNA are still not clear and need to be further investigated.

The mitogen-activated protein kinase (MAPK) cascade is a highly conserved module that is involved in various pathological functions, including neuropathic pain. At least four members of the MAPK family, ERK1/2, JNK, p38, and ERK5, have been identified. The role of spinal ERKs in nociception had been explored in the recent years. It is reported that the immunoreactivity of pERK1/2 can be used as a quantitative marker for sensitization or inhibition in the pain pathway at the spinal level.

It has been revealed that COX-2 is involved in the regulation of MAP kinase signaling. The p-ERK Level is downregulated after celecoxib treatment in the cirrhotic liver model of rats. The COX-2 inhibitor parecoxib exerts its analgesic effect on surgical pain through inhibition of neuronal ERK activation in the spinal cord. In the present study, we investigated the role of spinal ERK1/2 signaling in OXA-induced neuropathic pain. OXA increased the expression of pERK1/2 in the spinal dorsal horn neurons while celecoxib alleviated the OXA-induced hyperalgesia accompanied by the downregulation of pERK1/2. Thus, spinal ERK1/2 plays a vital role in OXA-induced neuropathic pain.

In conclusion, our study was the first to show that COX-2 and pERK1/2 were increased within the spinal cord after administration of OXA. A COX-2 inhibitor alleviated the neuropathic pain caused by OXA through inhibition of COX-2 and pERK1/2. These data illustrated that OXA can induce neuropathic pain, and this role of OXA was mediated by the COX-2 and pERK1/2 pathway.
